In all great centres of population it is clear there must always be a certain proportionate number of street accidents. It would be interesting to find out, were the basis of such an estimate obtainable what is the ratio of frequency of incidence of that special class of missadventure to the density of population. The figures recently issued for the metropolis seem almost to suggest that some such relation exists between the two sets of circumstances. The population of London multiplies at a rapid rate, and of recent years a great increase has taken place in the number of persons injured by accidents in the street. For instance, in 1891 and 1892, when the accidents in the day were 4,756 and 4,800, in 1900 and 1901 they reached 8,010 and 7,995. It is probable that the chronic state of obstruction which has been conspicuous in the main thoroughfares of the metropolis for years past is to some extent answerable for that fact. Another element is undoubtedly the multiplication both of traffic and of passengers. With regard to the first-mentioned condition, local authorities throughout the kingdom are prone to place the streets of their towns at the mercy of various corporations without imposing proper restrictions, such as that of continuous work by day and night, time limits, and so on, whereby the duration of obstructions might be reduced to a minimum. Then there is the nuisance of the "crawling" cabs, which impede traffic and add not a little to the dangers of the streets. Another matter that deserves further attention is the provision of footways over or under ground, at points where traffic is busiest. With the utmost exercise of precaution and vigilance on the part of a civil administration, however, a certain margin of street accidents must necessarily occur.

The Alcoholisation of Women.

Temperance reform is now taking its proper place as an essential part of public and personal health. Medical men of the highest distinction are realising that the findings of science have secured a sound basis on which educational effort may be built up. While drunkenness is to some extent diminishing other and more serious forms of alcoholism are on the increase. The saddest and most serious aspect arises from the growing alcoholisation of women. So imminent is the danger, and so subtle and insidious the growth of the drink habit among females in all ranks of society, that we are glad to see that so eminent an authority as Sir Thomas Barlow, physician to the King, on Thursday last at a public gathering in Westminster Church House, dealt with this matter from the medical and scientific standpoint. Sir Thomas, after indicating the more important causal factors which lead women into the thraldom of inebriety, denounced the severely pessimistic attitude of some in regard to the restoration of such, and showed that rest, removal of cause, avoidance of drugs and moral support, afforded sound and, in many instances, effectual treatment. Sir Thomas Barlow has rendered humanity a real service in showing that the best means of securing hygienic righteousness in relation to this matter is to permeate society with the knowledge that it is a superstition to hold that alcohol is needed for the ordinary work of life. We are glad to see that Sir Thomas Barlow advises the rigorous protection of inebriates from the pernicious influence of an alcoholic environment, and insists that they should only be entrusted to the care of those who are themselves abstainers from alcoholic beverages. It is a remarkable evidence of the awakened interest in measures for the prevention and arrest of alcoholism that the present number of *The Practitioner* should be devoted to the special presentation of this matter in a series of articles by experts of distinction.

Lady Practitioners at the Polyclinic.

It is announced that in future lady practitioners will be admitted to the systematic course of lectures at the Polyclinic and Post-Graduate College, although, by the constitution of the College, they are not eligible as members. The Council are careful to add that this does not entail their admission to the clinical demonstrations, an innovation of which they state there is "no probability," so that there need be neither fear on the one side, nor expectation on the other. We must confess that we are quite unable to discover valid grounds for such exclusiveness. It has been asserted that patients object to a mixed audience, but that is contrary to general experience, and the hypothesis that practitioners in general would resent the presence of fellow practitioners of the other sex is quite untenable. This is the only country in the world, we believe, where such restrictions are maintained, and it would be difficult to justify them on any grounds consistent with common sense.

The Staff of St. Bartholomew's Hospital.

Mr. Butlin, one of the surgeons at St. Bartholomew's Hospital, has carried out his intention, as we announced some weeks ago, of resigning his post on the staff. After the promotion of the senior assistant surgeon, a vacancy will be thus created on the assistant staff. For this vacancy we understand that there are so far two candidates—one the present Surgeon Registrar, and the other Mr. McAdam Eccles, of the West London Hospital, and the City of London Truss Society. The election for this latter post will probably not take place until January next, thus there is ample time for the candidates to indulge in that very trying ordeal—namely, a persona canvass of the Governors.

Synthetic Abominations.

The ease with which chemists now ring the changes in the synthesis of odours has flooded the market with a large and ever-extending series of so-called perfumes bringing them within the reach of the humblest. In the educated classes of society the doctrine of personal cleanliness has long since displaced the employment of perfumes which only had their *raison d'être* in the desirability of masking disagreeable emanations, but the need is still felt lower down in the social scale, hence the popularity of these cheap—and nasty—odours. If ladies would only bear in mind that the use of strong perfumes is presumptive evidence of their having an idiosyncrasy of the kind to disguise, they would, perhaps, be more judicious in resorting thereto, and so conduce to the general comfort of mankind.

Medical Men and Stirpiculture.

Medical men, as an educated professional class, are brought into close contact with the social life of the community. Their aggregate influence under these conditions is undoubtedly great, and it probably forms one of the powerful, yet unseen, educational forces at work among the nation. Galton, the well-known enthusiast in anthropology, desires to enlist the medical profession under his banner for the purpose of improving the physical fitness of the race by the science known as "Stirpiculture." He does not ask medical men to advocate the extreme steps of deliberately breeding man by artificial selection as we breed cattle, an experiment for which the philosophy of the world is either too young or too old. He suggests the more practical step of educating parents to consult their medical advisers as to the fitness of children for marriage, and for the production of children of good type. He even hints at the issuing of diplomas of special fitness for marriage by a joint committee of medical men and of lay anthropological experts. Although there is little prospect of his Utopian scheme ever coming into practice, nevertheless Galton does a great service to mankind by calling the attention of the medical profession to the importance of the marriage relationships of their patients to the community at large. Medical men are somewhat apt to lose sight of the wider aspects of their professional life in the hurry and rush of exacting and laborious work, which is but too often at the same time sordid and ill-recompensed.

Phantom Gall-stones.

The symptoms of active cholelithiasis are so strongly marked that it would seem impossible to go far astray in diagnosis. For all that, bedside experience shows that various conditions are apt to lead to error on the part of the medical attendant, who ascribes to the presence of gall-stones phenomena arising from other causes. Among these fallacies may be mentioned locomotor ataxy, which often simulates gall-stones pretty closely, and indeed, has led to operation in several recorded cases. If the medical man be on his guard, this source of error can readily be eliminated by noting the state of the pupils and of the knee-jerk. Right-sided pleurisy has frequently been mistaken for cholelithiasis. Lead colic, again, presents a clinical picture that sometimes leads the unwary into an interpretation of biliary calculus. Ulcer of the stomach is sometimes confused with gall-stones, as well as renal colic and gastralgia. A areful and systematic examination of the patient will in most cases enable the medical man to steer clear of most of the above fallacies. Now and then, however, an accurate diagnosis is impossible, except with the aid of an exploratory laparotomy. For example, without the evidence afforded by an attack of jaundice, it would be extremely difficult to form any trustworthy conclusion in many cases of chronic and severe gastralgia in young or middle-aged women. Among other conditions that have been mistaken for gall-stones may be mentioned various inflammatory states of the liver and biliary passages, as well as more general febrile conditions, such as malaria. Then, after all is said and done, there is always the possibility that gall-stones may be present as a complication of other disorders. The moral of the fallacious gall-stone is to be found in the teaching of constant watchfulness, and of the necessity of full and complete evidence before arriving at a definite diagnosis of gall-stones. The malady may be safely inferred if a patient has suffered often from typical colic, jaundice, biliary, septic conditions, inflammation of gall-bladder, and localised or general peritonitis. A correct diagnosis is of considerable importance, as in the more severe cases prompt surgical interference alone can save the patient from a serious or fatal issue.

Aneurysm Due to Tuberculous Lesions.

Although tuberculous inflammation of the walls of blood-vessels is very common, inasmuch as arteries and veins running through tuberculous organs are readily invaded by the disease, the tuberculous disease itself was not supposed to bear any relation to aneurysm. Even Læunce, in his classic description of multiple pulmonary aneurysm, ascribes the disease to want of support in the vascular walls and not to the tubercle which infiltrated them. In endarthritis the profession found a satisfactory theory for the disease, and reluctantly enlarged their view by adding Koster's mesartritis theory in 1873. To a limited extent simple atrophy and paralytic relaxation of the arterial coats were recognised, not to speak of such gross pathological lesions as syphilitic deposits, sclerosis, and calcification. In cases of tuberculous infiltration the resisting power of the wall of the artery was so weakened, and it had become so brittle, that the older pathologists concluded it would rupture under pressure, without previously becoming increased in its bore or pouching. So satisfied were they of this that they never looked for tuberculous deposit in an aneurysmal wall. M. Heller, however, has given a shock to our fixed ideas on the subject by describing a case of aortic aneurysm at the site of the superior mesenteric artery, which was clearly due to the presence of tuberculous deposit, and the tubercle bacilli found were numerous. When attention is directed to the subject there is little doubt but that other pathologists will confirm M. Heller's views.

Dr. Mary Scharlieb has just been appointed Consulting Physician for the diseases of women to the Royal Free Hospital in Gray's Inn Road.

The Treatment of Epilepsy.

One of the best-known of the monatomic alcohols of the fatty series is amylic alcohol, whose ester nitrate of amyl possesses such a marked influence on the circulatory system. The drug has almost fallen into disuse; its effects were too evanescent to make it of much value in general therapeutics. A new use has been found for the ester. It is proposed to use it as a prognostic means in cases of epilepsy, for those cases in which anæmia of the brain is present prior to and during an attack. Such cases as are benefited by the inhalation of the drug, particularly those cases in which an attack is aborted by its use, are such as Winter, Vidal, Jonnesco, consider would be benefited by resection of the cervical ganglia of the sympathetic, so producing a permanent cerebral bloodshottedness. Winter has collected 213 cases of sympathetic resection for the cure of epilepsy; of these 122 cases were carefully followed, of which number eight have for more than three years remained well; seventeen cases are reported as temporarily cured, this word implying that a period not longer than two years had passed since operation; twenty-three were improved, the attacks being markedly less in severity and number; seven died and sixty-seven were not improved. It is to be hoped that by the use of nitrate of amyl a better selection of cases may be made, and consequently a larger percentage of cases obtained. The cases benefited by the operation are, it should be remembered, just those least amenable drugs.

PERSONAL.

Mr. A. W. Mayo-Robson, F.R.C.S., having, as previously announced, resigned the Honorary Surgeonc to the Leeds Infirmary, has been elected Consulting Surgeon thereto.

The vacancy thus created on the surgical staff has been filled by the appointment of Mr. R. Lawford Knaggs, M.D., M.Ch., F.R.C.S.

Miss Mildred Heather-Bigg has been appointed Matron of Charing Cross Hospital. She was trained at University College Hospital, and is at present Matron of the Chelsea Hospital for Women.

A Royal medal has been awarded by the Royal Society to Professor A. Schäfer for his researches into the functions and minute structure of the central nervous system, especially with regard to the motor or sensory functions of the cerebral cortex.

Henry Maurice Tickell, M.A., M.D., B.C.Cantab., M.R.C.S., has been appointed Assistant-Physician at Dr. Hettinger's Sanatorium for Open-Air Treatment of Lung Diseases, Nordrach, Black Forest, Germany.

Lord Lister, full of years and honours, has received a further mark of distinction in the award by the Royal Society of the Copley medal. This is regarded as the "blue riband of science." It was founded in 1709 by Sir Godfrey Copley for distribution to the living authors of such philosophical research, either published or communicated to the society, as might appear to the Council to be deserving of that honour.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

MANCHESTER.

[FROM OUR OWN CORRESPONDENTS.]

The New Infirmary Board.—The election of a new Board of Management for Manchester's leading charity is now an accomplished fact. Its result is a striking vindication of those who, under the name of the Trustees' Committee, organised a campaign against the old Board and nominated twenty-one gentlemen to form a new one. One of their candidates withdrew his name, and nineteen out of the remaining twenty were duly elected. Thus the nominees of the Trustees' Committee form nineteen out of the twenty-one lay members of the new Board. Seven members of the old Board were elected, quite enough to secure decorous continuity of action. The popular gentleman who has for long acted as chairman of the House Committee was one of the independent candidates. He was elected at the bottom of the poll—another proof of the strength of the Trustees' Committee. His presence on the new Board will give general satisfaction, and no surprise will be felt should he remain chairman of the hard-working House Committee which manages the affairs of the charity from day to day. The three lady candidates have been left out in the cold. Seeing that it was they who forced a contest, and are thus responsible for the trouble and expense of an election, their position cannot but be rather humiliating. The new Board will doubtless at an early date make some arrangements by which their deliberations may be assisted by female intelligence.

The Medical Societies.—Last winter, what with endless committees of the British Medical Association and other interruptions, the societies were all somewhat depressed. The present season has begun much better, and the Medical, Pathological, and Clinical Societies have all held very large and satisfactory meetings. With growing memberships, sound financial positions, and plenty of good fellowship, these institutions promise to do better work than ever. The clinical meetings of the Medical Society are now to be held within the Royal Infirmary, which is certainly the best place for the attendance of patients for exhibition and for members.

BELFAST.

[FROM OUR OWN CORRESPONDENTS.]

The New Medical Institute.

Wednesday, the 26th of this month, will be a busy day for the members of the medical profession in and around Belfast, if the present arrangements for opening the Medical Institute are adhered to. According to these arrangements his Excellency the Lord Lieutenant will open the Institute at noon, Lady Dudley will unveil a memorial window to Dr. William Smyth in the afternoon, and in the evening the annual dinner of the Ulster Medical Society will be held in the Society's new home.

At the morning function the retiring President, Sir William Whitla, will hand over his office to his successor, Dr. John Campbell, and will then hand to the new President the title-deeds of the Institute, his gift to the Society, and the Lord Lieutenant will declare the Institute open. The afternoon ceremony will be for ladies, the wives of the medical men invited to the morning ceremony being invited to it. The details of this programme are not comp'ete yet, but both ceremonies promise to be most interesting.

The dinner will be held in the large hall of the Institute, which will accommodate about 140 if necessary, though about 120 will be more comfortable. To this dinner it is intended to ask a considerable number of guests, including some distinguished medical men from a distance, and some of the leading business men of the city who have shown a special interest in hospital affairs and medical education.

The Institute is now almost ready for the opening ceremony, and is a source of lively satisfaction to all the members of the Ulster Medical Society who have seen through it. It is situated in College Square North, with a frontage of 45ft. to the street and is about 46ft. high. The front is designed in Perpendicular Gothic and built of light-brown stone from the famous Scrabo quarry in Co. Down, with red Dumfries sandstone dressings. Entering through an outer and inner porch, one comes into the inner hall, which is about 24ft. by 16ft. In it the daily papers and lay journals will be kept, and there members may smoke and chat. Separated from it by a beautiful stone arcade, filled in with folding glass doors, is the library, 30ft. by 34ft. The special feature of this room will be the memorial window to Dr. William Smyth, which is effectively placed above the massive stone mantel. It faces the folding glass doors, so is seen from the hall as well as from the library. The library will, of course, be reserved for professional reading and work. Behind these rooms is a small office for the librarian, a council-room, cloak-room, and lavatories. On the first floor is the lecture-hall, about 43ft. by 30ft., and 16ft. high, with a musicians' gallery opening off it. The windows are all double, so as to minimise the sound of street traffic, and in every detail it has been most carefully planned to suit the needs of the Society. On the wall at one end are a permanent blackboard and lantern screen, and the tables used for dinners fold up and form the platform for less festive occasions. Behind the lecture-hall are kitchen and serving room.

On the second floor is the billiard room. On the same floor are the caretaker's apartments and another lavatory. The whole building is lighted by electricity. Perhaps the most striking point about the Institute is the beauty of the woodwork. It is a point to which the architect, Mr. William J. Fennell, M.R.I.A.I., loves to devote special attention, and as the generous donor of the Institute has marked artistic tastes, he has given the architect a very free hand in adorning the building in this way. One point more should be mentioned in speaking of adornment. On the front of the building are four beautifully cut heads, life size. They are Professor Redfern and the late Professors Andrews and Gordon, and Dr. Henry MacCormac—men who deserve to be long remembered by the medical profession in Ulster.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

FIBROIDS AND THE MENOPAUSE.

To the Editor of The Medical Press and Circular.

Sir,—The report of the meeting of the Obstetrical Society contained in this journal for November 12th credits me with the statement that I regard the belief that fibroids shrivel at the menopause to be a superstition. This is not correct. In reply to a question deliberately put to me by the secretary, I said it was a superstition that fibroids *disappeared* at the menopause. My views on this question are founded on a broad and careful study conducted for many years, and they are formulated in the subjoined extract from the second edition (1901) of my book on "Tumours," p. 217.

"It is not only true that fibroids arise during menstrual life, but it is equally certain that they influence menstruation, and I have operated on many cases in which this disagreeable phenomenon has been as profuse between fifty and fifty-five as it was at twenty.

"This fact does not in any way disturb the rule that when a woman with a fibroid in her uterus attains the menopause the tumour may cease to grow. That they disappear ('dry up' is an expression in common use) after the menopause is an event almost as rare as the advent of a comet.

"*Myomata sometimes take on an unusually rapid growth with the cessation of menstruation.*"

I am, Sir, yours truly,
J. Bland-Sutton.

47, Brook Street, Grosvenor Square.

Medical News.

Gordon Memorial College.

The Gordon Memorial College at Khartoum, recently opened by Lord Kitchener, has been presented with chemical and bacteriological research laboratories by Mr. H, S. Wellcome, and these will shortly be installed. Dr. Andrew Balfour has been appointed director, and advantage will be taken of the exceptional opportunity thus afforded for the study of tropical diseases.

Docking the Salary of a Medical Officer.

The Local Government Board have written declining to sanction a higher commencing salary than £120 for the medical officer of the City of London. It must be a very exceptional experience for the Board to have to criticise a salary on the ground of its being in excess; as a rule, its intervention is invoked in the opposite direction.

Dinner to Dr. Joseph Smith.

A complimentary dinner was given last week at the Trocadero Restaurant to Dr. Joseph Smith, in appreciation of his courage in coming forward, in response to the request of his brother practitioners, as a candidate at the recent election to the General Medical Council. Dr. Ambrose, M.P., presided, and complimented Dr. Smith on the way in which he had fought an unequal contest. The paragraph report of the dinner which went the round of the Press is headed "General Medical Council," which is rather misleading, for that body does not feed in public.

Fire at St. George's Hospital.

An alarm of fire was raised in one of the wards on the first floor at St. George's Hospital on Sunday evening, and created much excitement. Fortunately, the timely application of a few buckets of water extinguished the flames, and when the firemen arrived little remained to be done. The circumstances under which the accident occurred are to be closely investigated.

Deaths under Chloroform.

An inquest was held at Poplar last week on a man, aged 50, who succumbed to chloroform narcosis while being anæsthetised preparatory to amputation of a finger. A verdict of death from misadventure was returned.

A lady, the wife of an officer in the Army, died under chloroform last week at the Connaught Hospital, at Aldershot. The drug was administered for the purpose of attempting the reduction of an old-standing dislocation of the elbow, but death supervened before anæsthetisation was complete. At the post-mortem examination fatty degeneration of the heart was discovered.

Schedule of Standards for Pharmacopœial Preparations issued by the Local Government Board of Ireland.

We have received from the Irish Local Government Board a copy of the recently-issued schedule of standards for pharmacopœial preparations. The list is a small one, containing only 108 preparations, and many of the pharmacopœial preparations more used are not included, although some little-used ones find a place. We think the percentage of morphia present in the compound tincture of chloroform and morphia should be stated. Why aromatic spirits of ammonia, spirits of cajeput, and sweet spirits of nitre are left out is difficult to understand. The list is, however, intended for analytical chemists as a minimum standard; but we fear that contractors will take it as the maximum standard and neglect the higher standard of the Pharmacopœia. The list will have an injurious effect on the quality of the drugs supplied. At present the tendency of the trader prosecuted under the Adulteration Act is to declare that there is a "trade" standard as well as a pharmacopœial one. In the future he will flourish the Irish Local Government Board standard as an authoritative document in the face of the magistrate. It will be a strong proof that the authorities in Ireland considered the pharmacopœial standard too high, and refused to hold medicine contractors to it. The best thing to do with the list is to withdraw it from circulation.

Death from Cocaine.

An inquest was held at Rochdale last week on the body of Dr. Daniel McIntyre, of that city, as the result of poisoning by cocaine. It appears that the deceased had put some crystals of the alkaloid into an aching tooth for the relief of pain, and it is surmised that he must have swallowed it. A verdict of accidental death was arrived at, and great sympathy was expressed for Mrs. McIntyre and her family.

The Harveian Society.

The annual dinner of the Harveian Society of London will take place at the Café Monico December 11th, at 7 p.m. Mr. W. Cheyne will be in the chair. The following gentlemen have promised to be present:—Sir William Taylor, Sir Frederick Bridge, Sir James Reid, Sir James Crichton Browne, Colonel Stephenson, and the Presidents of the College of Physicians, Hunterian Society, Medical Society, Royal Medical and Chirurgical Society, and West London Medico-Chirurgical Society.

Precautions Against Measles.

The London County Council has been asked by the London School Board to extend to measles the provisions of Section 68 of the Public Health (London) Act, 1891, which prohibits, without proper precautions, the exposure in a public place of any person suffering from a dangerous infectious disease, and also the transmission of infected articles.

Miners' Anæmia.

The prevalence of anæmia among the miners at Dolcoath, Cornwall, has been investigated by the Inspector of the Local Government Board, and is found to be due to *dochmius duodenale*, a parasite not known to exist in this country, though common in Egypt.

Dublin Death-rate.

The deaths registered in the Dublin registration area for the week ending Saturday, November 8th, 1902, represent an annual rate of mortality of 31·4 per 1,000 of the population. Diseases of the respiratory system caused 57 deaths; diseases of the nervous system, 11 deaths; diseases of the circulatory system, 27 deaths; and 38 deaths resulted from tuberculous disease. Within the city in North Clarence Street district the death-rate was 36·8; in Summerhill it was 36·9; in Lisburn Street, 41·6; in Blackhall Place, 37·9; in South Earl Street, 38·1; in Castle Street, 51·8; and in Peter Street, 38 per 1,000. Ninety-six infants died during the week, of whom 45 were under one year old.

Trinity College, Dublin.

The following gentlemen have passed in Anatomy and Institutes of Medicine:—Henry H. A. Emerson, William Nunan, Thos. T. H. Robinson, John Chambré, Winslow S. S. Berry.

Royal College of Physicians and Surgeons.—Final Examination.

Candidates have passed this examination as undernoted:—A. Charles, F. H. Cooke, W. F. Delany, W. J. Greehy, D. Jones, F. J. Moore, R. C. Nicholl, T. J. Nicholl, W. J. O'Doherty, R. O'Flaherty, R. H. G. Oulton, P. W. Power, L. G. de Rosario.

Inadvertently omitted from the list of those who passed the Second Professional Examination, Part 2:—

Honours—E. L. Sheridan.

Pass—W. Sheahan.

Public Health:—With Honours—Miss E. A. Sproull, M.B., B.Ch., Edin. Univ.

Pass—C. L. Birmingham, M.D., R.U.I.; D. S. Browne, L.R.C.P. and S.Ed.; E. A. Husein, L.M. and S.; T. C. Lauder, L.R.C.P. and S.I.; Miss E. Macrory, M.B., B.Ch., Edin. Univ.; E. F. Stephenson, F.R.C.S.I.; J. G. Willis, L.R.C.P. and S.Ed.

Preliminary:—Honours—A. E. E. Davis, A. W. Hughes.

Pass—M. B. Dooly, J. Ellenbogen, F. E. G. Greer, H. J. Hedley, H. S. Johnston, P. D. McCreery, P. J. McKevett, C. McQueen, E. J. Quirke, E. Ryan, M. G. H. Sampson, L. D. Woods.

Notices to Correspondents, Short Letters, &c.

☛ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Dr. W. W. Murphy —The flower you sent is a specimen of *Anagallis arvensis* (Red Pimpernel, Shepherd's Hour Glass). It is not an uncommon herb in fields and waste places. We cannot state anything regarding its medicinal qualities, beyond that it is sometimes said to be poisonous.

THE EVOLUTION OF POSTERITY.

The responsible section of trans-Atlantic anthropologists and legislators have come to the practical conclusion that "the man of the future" is to derive his genesis from the great Mountain State. Accordingly the Colorado Legislature has applied itself to the realisation of this praiseworthy ambition, by introducing a law which permits only well-developed persons, of well attested physical and moral health, to enter into the bonds of holy matrimony. And, of the selected partners, the male must have attained a minimum age of twenty-five and the female of twenty-two. Both must be thoroughly free from personal or hereditary taint of tuberculosis, insanity, epilepsy, asthma, as well as all other kinds of organic or hereditary disease. They must not be more closely related than by the fourth degree of cousinship. No one will be allowed to marry without a proper certificate, and for the enforcement of this law, county boards of medical examiners are to be formed. It is hoped that by its means all persons of inferior physical and moral constitution will be debarred from the undesirable privilege of transmitting their infirmities to an unhappy posterity. And, as the *Medical Age* observes, it can now only be hoped that the praiseworthy citizens of Colorado will find it as simple a matter to dispose of a deep-seated evil as it is to propose a remedy. If Jove laughs at lovers' vows the attempts of legislatures to control Cupid's eccentricities must excite a rictus.

G. P. (Leeds).—We do not consider that the charge was excessive.

M.D. (North Shields).—A member of the Royal College of Physicians London is by the bye-laws of his College, prohibited from dispensing his own medicines. He labours under various other disabilities, which you will find duly set forth in the regulations.

Dr. Belbord.—We understand that steps are being taken to bring the case under the notice of the General Medical Council.

THE TREATMENT BY HIGH FREQUENCY CURRENTS.

Senex writes: "I should be obliged if any of your readers could inform me whether a neurasthenic patient would be likely to benefit from treatment by high frequency currents."

F.R.C.S —Our correspondent has failed to enclose his card. We cannot deal with anonymous communications.

ANOTHER ADVERTISING MEDICAL ASSOCIATION.

A correspondent sends us a cutting from a local newspaper announcing the opening of a "Medical Association" for the Chesterfield district, with a surgery at Cluman Gate. It is artfully worded in that it contains no direct appeal for members, but it is perilously near the line.

Meetings of the Societies, &c.

LONDON.

Wednesday, November 19th.

Royal Microscopical Society (20, Hanover Square, W.).—8 p.m. Paper:—Dr. P. E. Shaw: An Electrical Method of Taking Microscope Measurements. Demonstrations:—Dr. D. H Scott: The Microscope in Fossil Botany.—Dr. E. J. Spitta: An Apparatus for Obtaining Monochromatic Light with the Mixed Jet.

Thursday, November 20th.

Harveian Society of London (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Mr. A. Doran: Uterine Fibroids: Considered from a Clinical and Surgical Standpoint. (Harveian Lecture.)

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.)—Dr. Lewers: Cancer of Uterus.

Friday, November 21st.

Epidemiological Society (11, Chandos Street, Cavendish Square, W.).—8.30 p.m. Paper: Lt.-Col. A. M. Davies, R.A.M.C.: What is Climatic Disease?

Society for the Study of Diseases in Children (11, Chandos Street, Cavendish Square, W.).—5.30 p.m. Cases and Specimen will be shown by Mr. F. Deas, Dr. H. Ashby (Manchester), Dr. C. O. Hawthorne, and Mr. R. C. Dun (Liverpool). Paper:—Dr. G. A. Sutherland and Mr. T. Walker: A Case of Syphilitic Arteritis and Nephritis in an Infant.

Tuesday, November 25th.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C).—Dr. Patrick Manson: Sprue.

DUBLIN.

Friday, November 21st.

Royal Academy of Medicine in Ireland.—Medical Section—Dr. Finny: A Case of Erythema Marginatum. Paper:—Dr. Finny: Erythema Marginatm. Drs. Bewley and Scott: A Case of Lymphadenoma with Persistent Pyrexia. Dr. Travers Smith. A Case of Paroxysmal Tachycardia Associated with Epilepsy. Dr. Joseph O'Carroll: A Case of Paroxysmal Tachycardia.

Appointments.

Ahern, John M., M.B., B Ch., B.A.O., R.U.I., L.R.C.P. and S.I., Deputy Medical Officer, H.M. Prison, Liverpool.

Allen, R., M.B., B.Ch., R.U.I., Assistant Pathologist to the Royal Hospital, Belfast.

Beddard, A. P., M D.Cantab, Assistant Physician to Guy's Hospital.

Bond, Francis, M.D.Lond., F.R.S.Edin., Medical Officer of Health for the Thornbury (Gloucestershire) District Council.

Bridger, J. F. E., M.R.C.S., L.R.C.P.Lond., Medical Superintendent of the Small-pox Hospital, Pelican Island, Barbados, and Medical Referee to the General Board of Health of the Colony.

Cosgrave, F. R., M.D., B.Ch.Dub., Appointed District Medical Officer of the Rochdale Union.

Craig J., M.D.Dubl., Assistant in the Ophthalmic Department of the Royal Hospital, Belfast.

Davies, T. A., L.R.C.P.Lond., M.R.C.S., Assistant House Surgeon to the Newport and Monmouthshire Hospital.

Gregory, A., M.R.C.S., L.R.C.P., House Physician to the General Infirmary, Leeds.

Houston, T., M.D., R.U.I., Medical Registrar to the Royal Hospital, Belfast.

Milward, F. Victor, B.A., M.B., B.C.Cantab, F.R.C.S.Eng., Surgical Casualty Officer to the General Hospital, Birmingham.

Platts, Sydney, M B., B.Ch. Victoria, House Surgeon to the General Infirmary, Leeds.

Ryan, John P , L.R.C.P. and S.I., appointed Senior House Surgeon to Jervis Street Hospital, Dublin, *vice* Edmund Glenny, L.R.C.P. and S.I., resigned.

Saxton, E., L.R.C P. and S.Edin., L.F.P. and S.Glasg., Medical Officer and Public Vaccinator for the Trentham District by the Stone (Staffordshire) Board of Guardians.

Scatchard, T., L S.A., House Physician to the General Infirmary, Leeds.

Stansfield, F. J., M.R.C.S., L.R.C.P., House Surgeon to the General Infirmary, Leeds.

Vacancies.

Banstead Road School, Sutton, Surrey (for Ringworm Children, under the Metropolitan Asylums Board).—Visiting Medical Officer. Salary £100. Application to the Clerk of the Board, Embankment, E.C.

Beverley Dispensary and Hospital.—Medical Officer and Dispenser (non-resident). Salary £160 per annum. Applications to C. J. Arden, Clerk.

Hospital for Sick Children, Great Ormond Street, London, W.C. Resident Medical Superintendent. Salary 100 guineas per annum, with board and residence in the hospital and £5 washing allowance. House Physician. Salary £20, washing allowance £2 10s., with board and residence in the hospital. Candidates must be unmarried and possess a legal qualification to practise. They will be required to attend before the Joint Committees at their meeting on Wednesday, November 26th, 1902, at 5 p.m. precisely. Application to Adrian Hope, Secretary.

London Hospital, Whitechapel. E.—Medical Registrarship. Salary £100 per annum. Applications to G. Q. Roberts.

Middlesbrough County Borough Asylum, Marton-in-Cleveland, Yorkshire.—Assistant Medical Officer. Salary £130 per annum, with furnished apartments, board, and washing. Applications to the Medical Superintendent.

New Ross Union.—Medical Officer. Salary £125 per annum, together with the usual Vaccination Fees, one who will also act as Medical Officer of Health: salary, £15 per annum. Applications to P. A. Pope, Clerk of Union. (See Advt.)

Royal College of Surgeons.—Conservator of the Museum. Salary £105. Applications to James Robertson, Clerk of the College, 54, George Square, Edinburgh.

St. Pancras and Northern Dispensary, 126, Euston Road.—Resident Medical Officer. Salary £105 with residence and attendance. Applications to the Hon. Sec, H. Peter Bodkin, 23, Gordon Street, Gordon Square, W.C.

St. George's Hospital Medical School.—Secretary. Salary £150 with emoluments. Applications to the Dean of the Medical School, St. George's Hospital, S.W.

Worcester County and City Asylum, Powick, near Worcester.—Assistant Medical Officer. Salary £140 per annum. Applications to Medical Superintendent.

Yorkshire College, Leeds.—Department of Medicine.—Senior Demonstrator of Pathology. Salary £150 per annum. Applications to the Dean.

Births.

Musson.—On Nov. 14th at 15, King Street, Clitheroe, Lancs., the wife of Alfred W. Musson, M.B., B.C., Cantab., of a son.

Marriages.

Hay- Syms.—On Nov. 11th at Christ Church, Surbiton, Malcolm Bell Hay, M R.C.S., L.R.C.P., only son of the late T. B. Hay, of Christchurch, New Zealand, to Minnie, second daughter of F B. Syms, Esq. Lanreath, The Avenue, Surbiton.

Perry—Hull.—On Nov. 12th, at Blackmore, Essex, Frederick William Perry, L.R.C.P.I., M.R.C.S.I., to Ellen, younger daughter of Thomas Read Hull, of Jericho, Blackmore, Essex.

Sapwell—Ireland.—On Nov. 11, at the Church of St. Peter, Sheringham, Benjamin Beckham Sapwell, B.A., LL.B. M.B., B.C.Cantab, eldest son of B B. Sapwell, of Sankever, Aylsham, Norfolk, to Jessie Anna, youngest daughter of the late A. W. Ireland, Guestwick Hall, Norfolk,

ABSTRACT OF PAPER ON SUPRA-PUBIC CYSTOTOMY IN CASES OF TUMOUR OF THE BLADDER, WITH SPECIAL REFERENCE TO THE CAUSES OF MORTALITY AND OF RECURRENCE OF THE GROWTH. (a)

By CHAS. BARRETT LOCKWOOD, F.R.C.S.,
Assistant Surgeon to St. Bartholomew's Hospital.

SUPRA-PUBIC cystotomy in cases of tumour of the bladder has hitherto been almost the rarest abdominal operation in the practice of general surgeons. Since 1894 I have only performed the operation seven times, with one fatal result. But this statement by itself would give an erroneous idea of the mortality which has attended my operations. I can recall two antecedent ones at the Great Northern Central Hospital which both ended fatally. One of the patients was an old man whose bladder was explored, and found to contain a sloughing epithelioma; he died of pelvic cellulitis. The other was a woman who had two papillomata removed, and afterwards died of shock and suppression of urine. Thus, out of nine operation cases I have lost three. Presently the cause of this high mortality will be discussed, and then it will be seen that it is by no means exceptional for this class of case. The fate of the survivors was far from satisfactory. In the first the carcinoma was so extensive that I could not attempt its removal. In the second the extraction of a quantity of innocent papilloma was followed by suppression of urine and by a dangerous illness. In the third the pelvic lymphatic glands were felt enlarged during the course of the operation. The patient died thirteen weeks after the date of the operation from nephritis. (Operation April 29th, 1897; died August 9th, 1897.) In the fourth a papilloma was removed by forceps and elastic ligature on February 11th, 1899, and a small recurrence was seen with the endoscope on February 6th, 1902. In the fifth the papilloma was small and incrusted with phosphates. It was erased and burnt. Since her recovery she has had a child, and is now quite well, with normal urine. (Since February, 1902; date of operation November 25th, 1899.) Lastly, in the sixth a papilloma was seen with the endoscope at the mouth of the left ureter. When the bladder was opened the growth was found to have hidden an ulcer of the mouth of the ureter. On December 8th, 1900, the growth was removed and the ulcer cauterised. A year afterwards my friend Mr. John Gay told me that, although the patient was better, yet he occasionally had attacks of hæmaturia. Hereafter I propose to refer to these cases, because they throw light upon the cause of the high mortality, and also of recurrence of the growth. In addition, they illustrate points in the methods of operating. Their number is, however, far too small to justify any general conclusions, and therefore I have abstracted the notes of supra-pubic cystotomy in cases of tumour of the bladder from the Clinical Records of St. Bartholomew's Hospital from the year 1891 to 1900 inclusive. During this decade fifty-three operations were performed upon thirty-seven patients. Of these, thirty-two patients had one operation, two had two, two had four, and one had nine.

At the outset I propose to scrutinise the clinical material, to see what light it throws upon the question of mortality. This may be calculated either upon the number of *patients* or upon the number of *operations*. It is obviously of great importance not to confuse the two methods. If we take first the thirty-seven patients upon whom supra-pubic cystotomy was performed for tumour of the bladder, we find that twelve died and twenty-five recovered. Until these figures were seen I thought that the high mortality which had attended my own operations was exceptional. (a)

If we now calculate the mortality upon the total number of *operations* a more favourable result is obtained. Fifty-three operations were followed by twelve deaths and forty-one recoveries. The improvement in results is, of course, due to the recoveries of those patients who had repeated operations performed for the removal of papillomata. One man was operated on for the ninth time, two others for the fourth; and of two patients, who were operated upon twice, both died after the second operation.

In searching for the causes of this high mortality it is simpler to begin with the thirty-two cases in which a single operation was performed. Sixteen of these had the bladder tumour removed in one way or another, and in sixteen the tumour could not be removed. Three of the first class died and seven of the second. In other words, one set of sixteen with removable tumours had a mortality of less than one-fifth, and the other set of sixteen with irremovable tumours had a mortality of nearly one half. Such a striking difference suggests that in the last set some new and deadly complications must have arisen. In the three cases in which the tumour was removed, the cause of death in two of the three was sepsis, the onset of which seems to have been at or after the operation. Of the seven cases which died after one operation and without having the tumour removed, one died of shock and hæmorrhage, three died of sepsis, and three were not examined after death. Of the three septic cases, one died of pelvic cellulitis, one died of suppurative peritonitis, and one of prostatic abscess and pelvic cellulitis.

In one patient who died after a second operation, a year after the removal of the villous tumour the hæmaturia recurred, and was accompanied with rigors and high temperature. The patient died upon the fourth day after the removal of more villous growth, and extensive pelvic peritonitis was discovered. Its existence had not been suspected. The other patient, who had a second operation performed, died of ascending pyelo-nephritis with pyonephrosis. By adding to the three cases in which the tumour was removed six more in which it was not, we have nine cases in which the cause of death is known. Seven died of sepsis, one of shock, and one of shock and hæmorrhage. Clearly sepsis is the great danger of supra-pubic cystotomy in cases of tumour of the bladder; and after sepsis come shock and hæmorrhage, but they come a long way after.

(a) Read before the Royal Medical and Chirurgical Society, ovember 11th, 1902.

(a) Such, however, is clearly not the case. Sir Henry Thompson, operatng upon very severe cases by the perinæal route, had six deaths in twenty patients. "Tumours of the Bladder," 1884, p. 98, *et se*

I will now try to inquire how the sepsis occurs, and why it is so fatal. The alternatives are, first, that the sepsis may be present in the genito-urinary tract at the time of the operation; second, it may be introduced during the operation; and, third, it may enter after the operation. Unfortunately the clinical notes give no precise information upon these three alternatives; but, as a rule, they state whether the urine was acid or alkaline before the operation; whether cystitis had begun; whether the urine was mixed with pus or muco-pus; or the time when it became alkaline. It is well known that various kinds of bacteria may be present in the genito-urinary tract, although the urine which is passed is acid. But in the class of case under consideration, although it is not safe to infer that acid urine betokens asepsis, nevertheless we may assume that pus, muco pus, and alkalinity indicate sepsis.

If now we take again the patients who underwent one operation, and again divide them according to the removability or irremovability of the tumour, the results are as follows:—The condition of the urine is known in fourteen of the sixteen who had the tumour removed. In twelve the urine was acid, in two it was septic, but not in a high degree. Three of the twelve patients with acid urine died. I have already said that one died of shock, one of profuse and rapid hæmorrhage followed by pelvic cellulitis; and one of pyæmia following upon pelvic suppuration and ascending pyelo-nephritis. The two patients with septic urine both recovered. They were females, and, as it happened, were both under my own care. One had very slight sepsis, her papillomata being covered with a thin and recent deposit of phosphates. The other had an ulcerated and pedunculated epithelioma with a circumference of eleven inches. The sepsis was considerable, but I made determined efforts to disinfect the bladder. The condition of the urine was noted in thirteen of the sixteen patients with irremovable tumours. Three had acid urine and ten alkaline. A man with an irremovable ulcerated epithelioma had acid urine, but it contained pus and blood. He recovered from the operation, and all his urinary symptoms remained in abeyance for several months. A second patient with acid urine died of shock and hæmorrhage. The urine of the third patient was faintly acid before the operation. Death ensued from diarrhœa and hæmaturia. At the post-mortem examination suppuration was discovered in the psoas and iliacus muscles and in the pelvis, and the peritoneum was inflamed.

The remaining ten patients with irremovable tumours all had septic urine, and five of them died. As no post-mortem examination was made in two out of the five the cause of their death is unknown. Of the other three it is known that one died of suppurative peritonitis, one of cystitis, and one of extravasation of septic urine.

It may be remembered that two patients died after a second operation. One was septic before the second operation, and died of ascending pyelo-nephritis. The other had septic urine at the time of the second operation, and died of purulent peritonitis.

I shall not try to generalise from such a small number of cases; nevertheless I venture to point out one or two obvious conclusions. And, first, how much safer the operation of supra-pubic cystotomy is when the urine is acid and the tumour removable. Indeed, it seems reasonable to suppose that if shock and hæmorrhage could be prevented—and I believe that they could—the mortality would fall within very reasonable proportions.

Second, the cases clearly show the extreme danger of supra-pubic cystotomy when the urine is septic and the tumour irremovable. I have come to the conclusion that an operation is not justifiable under such circumstances. It is true that now and then a survivor experiences some relief from the horrors of the disease, but that relief is not worth attempting when the attempt entails a mortality of 50 per cent. Irremovable tumours of the bladder are almost invariably malignant. This was the case with fifteen out of sixteen under discussion, and it is almost certain that the sixteenth was also malignant. Now the ordinary course of malignant disease on any surface of the body is growth, degeneration and sepsis. In tumours of the bladder the growth is almost invariably accompanied by hæmorrhage, which may be fatal, but in any case predisposes to septic cystitis, and, indeed, to general sepsis. Further, the sepsis which complicates malignant disease is of a virulent type. Surgeons are well aware of its dangers. The only operation case I can remember to have lost from septicæmia had a foul and ulcerated carcinoma of the breast. While operating upon malignant disease complicated by sepsis the freshly cut tissues are sure to be infected, and the infection easily enters the blood-stream. I do not believe that the sepsis which complicates malignant disease of the bladder is more virulent than that met with in malignant disease of other regions, but, owing to the proximity of the ureters and kidneys, of the pelvic veins and cellular tissue, and of the peritoneum, it has unusual opportunities of doing harm.

Unfortunately, by far the largest proportion of bladder tumours are malignant. I have collated fifty-eight cases from the clinical records of St. Bartholomew's Hospital from the year 1891 to 1900 inclusive.

The diagnosis is based on information obtained by post-mortem examination, supra-pubic cystotomy, urethral dilatation, or clinical examination disclosing a growth in the bladder and secondary growths elsewhere. In many instances the macroscopic was confirmed by microscopic examination. Thirty-six of the fifty-eight cases were malignant, and in four of these the growth also involved the prostate. Eight were doubtful, but more likely malignant than innocent. Fourteen were supposed to be innocent. Three of the latter were discovered accidentally at post-mortem examinations. Two out of the three died from the effects of accidents, and one of cancer of the œsophagus. This gives a proportion of about four malignant or doubtful to one innocent tumour. But it is possible that these statistics are too favourable. Albarran (a) examined eighty-eight tumours of the bladder with the microscope, and found that seventy-one of them were malignant and seventeen were innocent, a proportion of about five malignant to one innocent.

The discrepancy is probably capable of simple explanation. I think we may assume that a good many tumours with thin pedicles have been thought innocent, especially in the absence of a microscopical examination. But it is now known that the thickness of the pedicle is not a trustworthy guide to the characters of the growth. Perhaps the slender-stalked villous papillomata may be an exception, but even they are at times associated with malignant growth. The extreme frequency of malignancy in tumours of the bladder, and the fallacy which underlies the naked-eye appearances, have an important bearing upon the methods of treatment.

The high mortality which attends supra-pubic cystotomy in cases of tumour of the bladder can be greatly lessened. In my own small experience it has been mainly due to the violation of the general principles of surgery. It is now almost certain that two of my fatal cases ought not to have been attempted. In one a huge irremovable malignant growth was found, and it was complicated with sepsis. Now surgeons will agree that if a malignant growth cannot be entirely removed it ought to be left alone. Nothing can be more unsurgical than to perform an incomplete, futile operation, and at the same time expose the loose cellular tissue and veins of the pelvis and the peritoneum to a virulent form of sepsis. In the second case the growth, although apparently innocent, was of at least twelve years' duration, filled the bladder, and was complicated with sepsis. The patient never rallied, and died on the third day. It is probable that he had arrived at the stage of ascending pyelo-nephritis. My third fatality was due to shock.

(a) "Les Tumeurs de la Vessie," Paris, 1892, p. 165.

Clearly, the proper time for operation is (1) before the growth is too extensive for removal and (2) before sepsis is established. Both of these requirements are fulfilled by an early diagnosis. This can in nearly every case be achieved. The growth would be seen if the bladder endoscope was systematically used after the occurrence of sudden spontaneous hæmaturia. Hæmaturia is the commonest and earliest symptom of bladder tumour. It was present in forty-three out of forty-five cases. In the two in which it was supposed to be absent the urine was not examined with the microscope. In about one quarter of the forty-three cases the blood was accompanied with pain. In about three-quarters the hæmaturia was preceded, accompanied, or followed by other symptoms, such as pain during and at the end of micturition, pain in the back, abdomen, rectum, vagina, root or end of penis, pubes, rectum, perinæum, and neck of bladder. Sometimes the hæmaturia was preceded by increased frequency of micturition, and sometimes was followed by retention or incontinence. Bits of growth were occasionally passed, or the urine contained suspicious epithelial cells. Unfortunately the first attack of hæmaturia soon subsides, and may not recur for months or even years, and the patient is supposed to have recovered. The absence of pain affords a false sense of security, and is an additional cause of delay in using the endoscope.

Although my own experience is so small, perhaps I may be allowed to refer very briefly to the details of the operation. In the first place, each step in the removal of the growth ought to be guided by the clearest vision, and for this a full-sized supra-pubic opening is required, aided by efficient retraction of the edges of the wound and by the use of an electric forehead lamp. Next as regards the removal of the tumour. Of late years a great deal of evidence has been accumulated, especially from the results of accidental wounds during laparotomies, or accidental rupture of the bladder, to prove that wounds of the bladder unite well and speedily provided that the operation is performed under aseptic conditions. The ideal of operation of supra-pubic cystotomy for the removal of tumour from the bladder ought in my opinion to fulfil the following conditions:—First, an early endoscopic diagnosis. Second, asepsis before, during, and after the operation. Third, the excision of the tumour, together with its base and a safety margin of healthy tissue. (*a*) Fourth, the closure of the wound left by the excision. Fifth, the closure of the supra-pubic wound. I have not endeavoured to discuss many important details; such, for instance, as the best suture material, or the conditions under which drainage is necessary above the pubes rather than by the urethra. In all regions of the body I am accustomed, when sepsis is present, to use biniodide of mercury catgut, and to provide abundant drainage. In addition, it is probable that fine catgut is the best material for all ligatures and sutures, except those in the abdominal wound, and also those which close the bladder.

Finally, I am convinced that, if the above five conditions were fulfilled, supra-pubic cystotomy for the removal of tumours would rapidly take its place in the same rank with the other successful abdominal operations, such as cholecystotomy or ovariotomy.

The King's Hospital Fund.

THE General Council, at their meeting on Monday, decided to distribute among the hospitals this year a sum of £100,000, or double the amount of last year's grants. It was determined that it should be devoted to the following four principal objects:—The opening of closed beds. The wiping out or diminution of debt. The carrying out of improvements by building or otherwise. The supply of various special needs and increased aids to general maintenance.

UTERINE MONOMA

(SOFT ŒDEMATOUS "MYOMA" OF LAWSON TAIT), COMPLICATED WITH THREE MYOMATA OF THE ORDINARY TYPE. (*a*)

By HERBERT SNOW, M.D. Lond., &c.,

Senior Surgeon, Cancer Hospital.

I INVITE the attention of the Society to a specimen which, if not unique, at any rate shows an extremely rare condition, and I doubt if anything similar has been previously exhibited here.

It will be remembered that Lawson Tait strenuously insisted upon the fundamental distinction between the solitary uterine tumour, which he designated "soft œdematous myoma," and for which I have lately ventured to propose the more convenient term "monoma," and the common uterine fibroid, or fibro-myoma. He pointed out that the monoma was always solitary; was always steadily progressive towards death, which it caused within a short term of years; was accompanied by severe and continuous hæmorrhage; was more painful, and attended by relatively acute symptoms. On the other hand, the much more prevalent uterine myoma is always multiple, need not involve any symptoms whatever, slowly grows throughout a very prolonged period, is never fatal except indirectly, as by bulk or degenerative phenomena. There is thus a wide gulf, clinical and pathological, between the two varieties.

In the specimen before you both forms of tumour are found to coexist. We have a round, softish, central mass as large as the fœtal head, giving rise to obscure fluctuation, which indeed was so marked that a colleague who assisted me at the operation urged me, after the abdomen had been opened, to insert a trocar before proceeding further. When I first saw the case in the out-patient room, I regarded it as an ovarian cyst complicated with fibroids; though as soon as the patient was anæsthetised I had no difficulty in diagnosing a solid growth. Then, with this you see multiple myomata of the ordinary pattern, solid and firmly organised.

The texture of the large monoma is soft, very vascular, and embyronic. The finger can readily be pushed into the soft pulpy tissue. At each corner of the fundus is a hard, tough myoma of the size of a small orange, sessile and interstitial. Behind one of these is another, smaller, attached to a thin pedicle.

The microscope shows the monoma to consist of non-striped muscle-fibre, with large nuclei, and very numerous leucocytes; to be, in short, much more embryonic in structure than the ordinary myoma, and to be passing into myo-sarcoma.

Case.—Emma F., æt. 42, married, four children (had had a miscarriage), admitted into the Cancer Hospital, August 23rd, 1902. A ruddy, robust-looking country-woman, wife of a miller. Previous good health: last child born thirteen years previously. No family history.

The symptoms were of four years' duration. For a long time there had been almost incessant vaginal hæmorrhage, so the patient stated, though there was nothing in her aspect to show this. Severe aching lumbar and abdominal pains, worse at the periods, and with movement. A huge irregularly shaped mass distended the abdomen. Some of the tumours were hard, but one appeared to fluctuate. They were mobile and slightly tender on pressure. The growth was rapidly increasing in bulk.

On incision, there were no adhesions, but the

(*a*) Obviously this proviso is difficult to fulfil when growth is at the orifice of the ureter, but even there, I believe, we might proceed boldly provided the cause is not a septic one. Also it cannot be fulfilled in cases of general villous papillomata.

(*a*) Read before the British Gynæcological Society, November 13th, 1902.

veins of the broad ligament on each side were enormously distended, and all the tissues highly vascular. The mass was dissected out from the cervix by the flap-operation, the flaps being subsequently sutured. It was necessarily prolonged, in view of the vascularity, as well as of the fact that the growth was deeply lodged in the pelvic cavity, and could be only partially delivered. The abdominal wall was closed in two layers, after a pint of saline fluid had been poured into the cavity. The next day the house-surgeon found an excessively frequent pulse, and injected a pint of saline fluid into the rectum with much benefit. Recovery was subsequently uninterrupted. The patient was discharged well on October 11th.

UNREDUCED SUBCLAVICULAR
DISLOCATION OF THE
HEAD OF THE HUMERUS.(a)

By EDWARD H. BENNETT, M.D., F.R.C.S.I.,
Professor of Surgery in the University of Dublin; Surgeon to Sir Patrick Dun's Hospital, Dublin.

The specimen which I submit to the Academy is a dissection of a shoulder-joint deformed by old unreduced dislocation of the head of the humerus, and with it a cast of the limb taken before its dissection. Of the life-history of the case I know nothing, and speculations as to the reason for its having escaped reduction are useless. The body is that of an aged female A view of the specimen and of the cast make it evident that the dislocation is to be named "subclavicular." The upper extremity of the humerus is seen to be placed directly beneath the clavicle, and to be remote alike from the glenoid cavity of the scapula and the coracoid process. The cast shows also a feature of the deformity of the limb characteristic of subclavicular dislocation, as contrasted with the intra-coracoid and other forms of antero-internal dislocations.

The limb lies in contact with the side of the thorax; to use the description of Malgaigne, "the arm is generally glued against the trunk." We can, in the cast, see this attitude of the limb, and the bearing of the tumour formed by the head of the bone. Looking at these relations of the parts chiefly involved in the dislocation, one is forced to the conclusion that when the dislocation occurred the whole, or nearly the whole, of the capsular ligament of the shoulder was ruptured, or stripped from its attachment to the bone around the glenoid portion of the scapula, necessarily most completely on the outer side of the joint.

The specimen shows that the head of the humerus passed into the bottom of the sub-scapular fossa, pushing before it, and to the inside, the sub-scapular muscle, which, with its tendon, is entire. Before the dissection had disclosed these parts, it was only evident that the dislocated head of the humerus could not be felt in the axilla, nor probably through its wall. The long head of the biceps muscle was torn by the dislocated humerus, and is adherent to the bicipital groove. I obtained this specimen in July, 1900, and it lay by me undissected for a time. In the spring and summer of 1899 I met two cases of dislocation in the living, which agreed in all particulars with it, so far as one can trace the similarity between the living and the dissected specimen. I should say that before 1881 I had been well experienced in the reduction of shoulder dislocation by the method of the heel in the axilla. I knew that to succeed by that method in difficult cases it was necessary to bring the heel, carried into the armpit, into contact with the displaced head of the humerus, and to use it as a fulcrum on which to lever the dislocated bone into its place. I may now mention that in attempting this movement I could not reach the head of the bone in either of the cases I am recording, nor, indeed, could I pass the heel at all upwards into the armpit. The arm glued to the side absolutely prevented this.

After I had heard Kocher, at the International Congress in 1881, describe his method of manipulation in treatment of shoulder dislocations, I applied it here with invariable success in reducible antero-internal dislocations, until I met the two cases I now submit. I did not, of course, apply it to posterior dislocations, for which it is manifestly unsuitable, of which I met in the time two cases.

The first of the cases I would now record was that of a powerful man, over six feet in height—a gentleman constantly engaged in active country life. He was mounted on a young horse, going to a meet, when someone handed him a paper. To read this he let his reins loose on the horse's neck, and as he read, the wind fluttered the paper, and the horse made a sudden plunge, throwing his rider heavily on the shoulder. Being near surgical help, he almost at once was placed under treatment by a very able and experienced surgeon, who got to help him three or four of the Royal Irish Constabulary, whose barracks were at hand. The attempt failed, and the patient telegraphed to me to meet him at one of the private hospitals that evening. I found that the dislocated limb presented the feature of an arm glued to the side, and that I could not reach the humeral head in the axilla with my fingers, while the tumour beneath the clavicle was distinct, though masked by powerful muscles. I tried the movements of Kocher's method, and failed. I determined, as the patient had had a bad few hours with his fall, the attempt at reduction tried in force, and his railway journey, to let him rest that night, and be ready in the morning to take an anæsthetic, when I could have with me sufficient assistance. In the morning I found that Kocher's movements again failed, and the failure was repeated when ether was fully given. I then tried the heel in the axilla, but, do my best, I could not reach the head of the bone, nor could I by traction bring it down to meet my heel. I then changed the method, making traction, against efficient counter-extension, on the arm abducted downwards and outwards, with lacs fast to the wrist and above the elbow-joint; by alternate rotation back and forwards. While I kept up the strain on the limb, I made it move with what is best described as a screwing movement, which in a few minutes ended in complete reduction.

The next case is of the same kind. The patient was a man over six feet in height, who had, in his youth, been a great athlete; he is now past middle life. I approached the case with misgivings. Already five weeks had elapsed since the occurrence of the injury—a heavy fall on the shoulder; and already five attempts had been made at reduction under anæsthesia, with four or five surgeons present each time, without any signs of reduction appearing. The features of the injury were the same as I have just now put before you—a tumour under the clavicle well to the inside of the coracoid process, an arm glued to the side, and the axilla closed by the shaft of the humerus, which prevented the hand or the heel from reaching the head of the bone. When I had the patient fully under ether, I tried Kocher's movements, without result, except that probably the head of the humerus was somewhat freed from adhesions. I tried the heel in the axilla, as in the last case, and because I had been so familiar with the method. I could not enter the axilla at all with my heel. I then tried the extension of the arm extended downwards and backwards. I found on making the screwing movements, as before, that the head of the bone came down, and was slowly reduced into the joint. I confess that the result astonished me. I believe that the head of the humerus could not get inwards to the distance at which it lies in the specimen without a great rupture of the capsule, first on the inside of the joint, through which the bone escapes and passes beneath the sub-scapularis, and again by the tearing away of the outside of the structure to permit the bone to take its new position. We see in this dislocation that the bone passes right away from the glenoid process of the scapula. In the other antero-internal dislocations the humerus rests by its groove between the head and great tuberosity on the glenoid border. The varieties of these lesions depend on the height or lowness of the contact between the bones in this groove and on the degree of rotation enforced on the shaft of the bone by the extent of untorn capsular ligament.

(a) Read before the Section of Pathology in the Royal Academy of Medicine in Ireland, on Friday, November 7th, 1902.

Looking at a model in which the parts of the ligaments are taken by elastic cord and membrane, we can see the reason why Kocher's proceeding fails, there being no structure left to act in maintaining the tension between the glenoid border and the humeral groove. Farabeuf's experiments demonstrate this point also, for if the external parts of the capsule be divided, the leverage necessary to the production of Kocher's reduction fails.

Austrian Clinical Lectures.

THE TREATMENT OF ARTERIO-SCLEROSIS BY SUBCUTANEOUS INJECTIONS OF ORGANIC SERUM.

By Dr. TRUNECEK,
of Prague.

[*Specially translated for* The Medical Press and Circular.]

Among the salts of the alkaline metals and earths which enter into the composition of blood serum, of which sodium chloride is the chief constituent (70 per cent.), there exists a certain proportion of phosphate of lime. This compound is insoluble in distilled water, but, on the contrary, dissolves easily in salt water, and also in solutions of sodium and magnesium phosphate, salts of which ordinary serum contain very small quantities (0 gr. 15 centigr. of one, and 0 gr. 48 centigr. of the other per cent.). We may assume, therefore, that it is to the presence of sodium chloride and in part to that of the alkaline phosphates, that phosphate of lime is found in a state of solution in blood serum. We may add, with regard to the sodium chloride, that all the tissues of the organism embody a rather large quantity thereof, but according to Bunge, this salt, at any rate, in the mammifera, is the more abundant the younger the animal.

These facts of biological chemistry, which we have deemed it desirable to mention, serve as a basis for the establishment of a rational treatment of certain pathological states—and more particularly of arterio-sclerosis—a condition directly associated with the deposit of phosphate of lime in the vascular walls. I must admit that it is impossible to prove conclusively that this precipitation is due to a deficiency of sodium chloride in the juices of the organism; but this, perhaps, we may take for granted, if we remember that the affection generally occurs in elderly subjects—that is to say, in persons whose organisms are comparatively poor in sodium chloride, whose urine is strongly acid, a sure sign of an insufficient quantity of alkaline salts in the blood. It seems natural enough, then, that in the therapeusis of this morbid state we should first of all endeavour to remedy this insufficiency.

To attain this end, the mere exhibition of chloride of sodium is not always sufficient, since it does not modify the alkalinity of the blood, which is very often reduced in these affections. The other salts of the serum which are equally endowed with an alkaline reaction (*e.g.*, sodium carbonate) are not any more likely to bring about the required change, even when taken in doses that render the urine alkaline. We must therefore have recourse to both chloride and carbonate of sodium; but the latter salt cannot be introduced through the stomach, the free hydrochloric acid of the gastric juice changing it into chloride. We are therefore constrained to administer it either by subcutaneous or intra-venous injections.

Lastly, it is essential that the substances thus administered should be quite harmless in their effect on the organism. In order to realise this desideratum, I tried all the alkaline salts which normally constitute the inorganic portion of blood serum. I prepared a mixture in which their respective proportions were the same as in the serum; I then made a solution six times as strong as the physiological fluid. To this solution, of which the formula is as follows, I have given the name of "inorganic serum":—

Sulphate of sodium	0 gr.	14 centigr.
Chloride of sodium	4 „	92 „
Phosphate of sodium... ...	0 „	15 „
Carbonate of sodium	0 „	21 „
Sulphate of potassium ...	0 „	40 „
Distilled water	Q.S. for 100 grammes.	

It is a clear, transparent liquid, with a saline taste and alkaline reaction; the saline constituents are 6·12 per cent., its specific gravity (at 20° C.) is 1·04. When it is injected into the circulation, in healthy subjects, the salts which it contains are rapidly diffused through the tissues and eliminated by the kidneys. In order, therefore, to render this absorption slower, I had recourse to subcutaneous injections, which I made as a rule in the forearm. These injections are well borne, and locally, they only give rise to an insignificant amount of pain which soon subsides.

I should have been glad to have been able to relate some instances of patients treated by this method. Unfortunately in the case of arterial sclerosis, there is no constant objective sign which enables us to demonstrate the existence of this affection. Pronounced changes in the aorta and large vessels may exist without any perceptible induration of the superficial arteries, and without any tangible hypertrophy of the left ventricle; moreover, it is by the alleviation of the subjective disturbances, especially of cardiac asthma, that are manifested the good effects of a treatment directed against arterio-sclerosis. Allow me, for this reason, to relate, first of all, the following case, in which the improvement was rendered manifest by physical signs which afforded conclusive evidence thereof.

In April, 1900, I was consulted by a man, æt. 44, big and well built, but cachectic. A year previously he had suffered from pain in the right arm, which, five months later, began to waste, together with loss of muscular strength. At the same time, a pulsating tumour made its appearance just above the right clavicle. This was diagnosed to be an aneurysm of the sub-clavicular artery, for which ligature was proposed, but the patient refused any operation. Little by little the symptoms became more marked, the dyspnœa and palpitation grew so intense that walking became almost impossible. When I saw the patient, in addition to the symptoms of arterio-sclerosis of the superficial arteries and hypertrophy of the left ventricle, I noted the existence, on a level with the second rib on the right side, and on the parasternal line, of a pulsation visible to the eye, synchronous with the cardiac systole; similar pulsations were visible in the sub-clavicular fossæ of the same side. Furthermore, just above the internal third of the right clavicle there was a pulsating tumour the size and shape of a chestnut, which also pulsated synchronously with the beating of the heart. Its lower part disappeared behind the clavicle. The right limb was weakened and slightly reduced in size; the atrophy affected more particularly the thenar eminence; the flexors of the fingers were paretic, the terminal phalanges were clubbed, and there was desquamation of the epidermis over the arms and trunk.

In the presence of these symptoms I diagnosed the case as one of aneurysm or dilatation of the ascending aorta, and aneurysm of the right sub-clavicular artery, accompanied by compression of the brachial plexus and the carotid artery of the same side, and I prescribed iodides. But this treatment, at the end of three weeks, having no effect, I decided, on May 9th, to make a first injection of a third of a cubic centimetre of inorganic serum, without, however, discontinuing the administration of sodium iodide. I repeated the injection ten days later, increasing the dose to 1 c.c. A few hours later the patient stated that the dyspnœa and distressful sensations over the heart, particularly the pulsations, had disappeared; but this improvement was not corroborated by any objective sign. The injections having been well borne, I repeated them thenceforward, every four or five days, increasing the quantity each time of liquid injected by a fifth of a cubic centimetre. At the sixth injection the pulsations felt in the second intercostal space had very much diminished in intensity; at the end of seven weeks, when the patient had received, altogether, 12 c.c. of inorganic serum, they had completely ceased, and they have not reappeared since.

The treatment was persevered with. In September the size of the sub-clavicular tumour had considerably diminished, while the paretic phenomena in the right arm had improved. Little by little the general condition also improved, and all the bodily functions were discharged normally. From the beginning of November, the total amount injected being then 120 c.c., the epidermic desquamation ceased and has not since reappeared. Up to the present his general condition has continued in a very satisfactory state, in spite of an intercurrent attack of influenza, and in spite of the fact that no injections have been made for more than three months. Locally, the sub-clavicular tumour still exists, but you will see by the two diagrams which I hand round that its dimensions have been considerably reduced; a slight pulsation is perceptible in the sub-clavicular fossa: the pulsations over the second side have completely disappeared; and, lastly, the thenar eminence is still atrophied. Altogether the patient has received 190 c.c. of inorganic serum in fifty injections.

I could mention many similar instances of the efficacy of this treatment of manifestations of arterio-sclerosis. The same result was obtained in the case of an old man, æt. 74, suffering from arterio-sclerosis and hypertrophy of the left heart, in whom the dyspnœa underwent marked improvement from the commencement of the treatment. Unfortunately I was only able to make three injections. A similar result was obtained in the case of a woman, æt. 33, suffering from arterio-sclerosis and anæmia; the dyspnœa disappeared completely and permanently after the patient had received 5 c.c. of inorganic serum.

I treated in the same way an individual, æt. 59, an alcoholic subject, who, five years previously, had had an attack of apoplexy. The disturbance consequent upon this had diminished to such a degree that walking had once more become possible, when, in August, 1900, tumefaction of the left foot and knee took place, against which all treatment proved vain. The patient was compelled to keep his bed, and his condition became steadily worse. It was in November, 1900, that he came under my care. He was in a very pronounced state of cachexia; the arterio-sclerosis was accompanied by hypertrophy of the left ventricle; there was purulent arthritis of the left foot and ankylosis of the left knee. The epidermis all over the body was desquamating freely. The urine was strongly acid, and contained uric acid in excess; the patient ate very little and was unable to sleep.

I started the treatment in the middle of December. After the second injection the man was enabled to sleep; at the end of two months, after having received 16 c.c. of serum, he had recovered his appetite and his general condition had improved. The diseased foot and knee had very much diminished in size; later on all the fistulæ of the foot closed, and this without any kind of local treatment; lastly, the proportion of urates and the urinary phosphates markedly increased. At the present time the total quantity of serum injected amounts to 58 c.c.; the patient, who had been unable for eighteen months to leave his bed, begins to walk about; the desquamation of the epidermis is still appreciable, but is diminishing; and the knee and foot have almost returned to their normal size.

The following is the manner in which I apply the treatment: I generally start by a dose of 1 c.c., then I repeat the injections every four or seven days, increasing on each occasion the quantity of serum by about 0 c.c. 20, and, when I intend to inject more than 1 c.c., I make several small injections to avoid too great a distension of the skin; I first of all inject 0 c.c. 5 or 1 c.c., then, leaving the needle in position, I wait several minutes before repeating the injection. When the dyspnœa is particularly distressing I do not hesitate, in order to afford relief, to repeat the injection every day. Up to the present the largest quantity I have injected at any one time is 7·5 c.c. Usually it is unnecessary to exceed 5 c.c. Even these large doses are well borne. The painful swelling which follows the injection soon disappears, and in no case did any abscess or acute inflammatory phenomena follow.

With reference to the effects of this treatment this method specially acts on the dyspnœa, which is sometimes calmed by the injection of mineral serum even more so than by the subcutaneous injection of morphine; as a rule the cardiac asthma is also improved, sleep and appetite return, and the general condition improves. In regard to the symptoms of arterio-sclerosis, if it is true that they appear to retrogress in certain cases, but we must not measure the success of the treatment by its effects in this direction but rather by the changes brought about in the general condition.

This therapeutical method appears to be indicated in persons suffering from arterio-sclerosis, whose blood is impoverished in alkaline salts. This does not signify that the alkalinity of the blood is reduced; as a matter of fact the proportion of chloride of sodium may be greatly below normal without any change in the reaction of litmus paper as evidenced by hyperacidity of the urine. On the other hand, a neutral or alkaline reaction of the urine—which is rarely observed in persons suffering from arterio-sclerosis—constitutes a contra-indication of the use of the inorganic serum. To sum up, the degree of the urinary acidity—as well as the desquamation of the integument—will be the chief signs on which we must rely, to commence, suspend or recommence the treatment.

It now remains for me briefly to explain the mode of action of injections of mineral serum. I have already explained the influence which alkaline salts exert in respect of the solubility of phosphate of lime which encrusts the vascular walls of persons suffering from arterio-sclerosis. This chemical action is also exerted on the fibres of the myocardium, the nutrition whereof, under the influence of the inorganic serum, is rendered easier, while their contractility and elasticity are increased, hence the regulating effect on the cardiac function.

One of the symptoms which soonest yields to the injections in question is dyspnœa. This fact may be explained by the increase in the alkalinity of the blood. As a matter of fact, we know that many oxydations cannot take place except in an alkaline medium, or are, at any rate, facilitated by such a medium. In addition to this the property possessed by blood plasma of absorbing the carbonic acid arising from organic combustion is also enhanced by the alkalinity of the blood. Now, it is well known that free carbonic acid, by its special action on the respiratory centre of the medulla, is the immediate cause of the dyspnœa, and this is withdrawn when the gas is converted into a salt.

This same excess of free carbonic acid (and other acid products of decomposition) provokes in the tissues a state of fatigue, which manifests itself in muscular tissues by a loss of contractility, and in the elastic tissue by a loss of elasticity. It is doubtless due to a similar change in the patient, whose history I have just been relating, that there occurred a dilatation of the arch of the aorta, the walls of which are, as we know, principally composed of elastic tissue; this also explains the decrease in size of the tumour under the influence of mineral injections.

Moreover, the good effects of this treatment may be attributed on one hand to the direct action of salts of sodium, and particularly of the chloride, on the heart. Potassium also acts on this organ, but as an antagonist of sodium. We must always bear in mind that the toxicity of the salts of sodium is about twenty times less than that of potassium; now it is exactly in the proportion of twenty to one that the salts of sodium and potassium exist in the blood serum, and consequently in the serum I employ.

Lastly, the cases related above show that the salts of alkaline metals in excess in the blood, especially chloride and carbonate of soda, have a favourable influence on the formation of normal epithelial tissue—we are also justified in hoping that, in a similar manner, the injections of inorganic serum may assist in the regeneration of the vascular endothelium, which has undergone changes during the evolution of the arterio-sclerosis.

In conclusion, I think I may state that the method which I have recommended, by raising the proportions of the alkaline salts in the blood and by increasing the alkalinity of this liquid, renders soluble the phosphate of lime which has been deposited upon the arterial walls, increases the activity of organic combustion, restores the intercellular exchange to approximately their normal standard, and consequently regulates the functions of the various systems, especially those of the heart and the blood vessels.

Clinical Records.

CHOLEDOCHOTOMY FOR CHRONIC JAUNDICE WITH CHOLANGETIS. (a)

By Mr. Alban Doran, F.R.C.S.,

Surgeon to the Samaritan Free Hospital, &c.

The patient had suffered from four or five attacks of jaundice when a child. When 33 years of age she had an attack of pain, and for the first time passed gall-stones. For two years the patient continued to pass about one stone per month without any jaundice, but with considerable pain.

On April 23rd, 1902, the patient, then æt. 36, came under Mr. Doran's care in the Samaritan Hospital. She was jaundiced, and the gall-bladder was enlarged and hard. The motions were quite pale, with a remarkable quantity of powdery matter, which proved to be of vegetable structure.

On May 1st an operation was performed. An incision was made, the gall-bladder was aspirated, and an ounce of thick greenish pus came away. The common duct was found much dilated, and just above the duodenal orifice a stone was impacted. A vertical incision was made into the dilated duct, and a rough, spherical calculus, three quarters of an inch in diameter removed. With the probe no other calculi could be found. The duct was sutured, a drainage tube placed in the gall-bladder, a plug of gauze passed under it and pressed against the common duct, and the upper part of the abdominal wound was closed.

On the third day after the operation, two soft calculi came away. On the fifth day there was severe vomiting, a rise of temperature and a pulse-rate of 140. On the sixth day much deep yellow bile escaped from the wound, and the vomiting ceased entirely. At the end of three weeks the patient was convalescent.

Two months after the operation there was some suppuration, and a piece of ligature came away. During September three pieces of calculus came away from the fistula, which is now only two and a-quarter inches in length.

Remarks.—This case showed the value of choledochotomy, an operation first performed by Courvoisier thirteen years ago. Choledochotomy was an ideal operation. A sand-bag under the loins proved a great assistance in pushing the duct forward. A long incision should always be used. The gall-stones which came away after the operation were probably hidden in the gall-bladder. The acute attack on the fifth day was probably a relapse of the cholangetis. The vomiting was extremely severe, but without symptoms of septic peritonitis. A fistula connected with the common duct, which fortunately did not occur in this case, was much more serious than one into the gall-bladder. There ought, however, to be no difficulty in suturing when the patient is placed in the proper position. Mr. Doran asked for opinions on the value of calcium chloride for increasing the coagulability of the blood. He thought the passage of quantities of sand-like powder of some interest. He also called attention to the fact that pregnancy favours cholelithiasis.

FRENCH HOSPITAL AND DISPENSARY.

Ectopic Pregnancy in left Broad Ligament with Secondary Rupture into Peritoneal Cavity necessitating Operation. (a)

Under the care of Mr. R. O'Callaghan.

The patient, æt. 33, was admitted to the French Hospital on October 20th, suffering from abdominal pain.

Condition on Admission:—The patient complained of great pain in the lower part of the abdomen, which had been present for a month before admission. She said she had always been regular, but had lost very little the last two periods, and that she was perfectly well until a month before admission, when she was suddenly taken ill with violent pain in the abdomen after having been out for a walk. A doctor was at once sent for, who diagnosed a ruptured ectopic gestation.

On Examination:—A large solid tumour was discovered, round and smooth except on the left side, where a lump about the size of a large orange could be felt. This tumour presented the appearance of a uterus three months pregnant. There was great tenderness on palpation, especially on the left side. On examining the breasts, the primary areola could be clearly distinguished and milk also squeezed from the breasts. Per vaginam, there was a bulging down of the left fornix of the vagina, and this bulging was found to be continuous with the tumour felt in the abdomen. The patient was very constipated, and the bowels were opened by means of enemata.

(a) Read before West London Medico-Chirurgical Society, November 7th, 1902.

(a) Read before the British Gynæcological Society, November 13th, 1902.

Course of the case.—After the administration of enemata the lump which was found on the left side of the tumour disappeared, showing that it was most probably caused by an accumulation of fæces. The patient continued to complain of great pain in the abdomen, and on October 28th there had been no passage of fæces or flatus for twenty-four hours. The pulse ran up to 142 per minute and the temperature to 102°. The patient became blanched and the respirations quickened and sighing in character. Vomiting also set in. A diagnosis of intestinal obstruction was made, and when I arrived at the hospital the woman was very ill, but ready for operation. On opening the abdomen below the umbilicus, the first thing found was fresh arterial hæmorrhage, the tumour then presented with the left tube on top of it dark in colour and congested.

The tumour proved to be an extra-peritoneal hæmatocele in the left broad ligament, which had moved over to the middle line, pushing over the uterus. The broad ligament was opened up at the point of secondary rupture. The blood-clot (about two pints in all) was removed, and the gestation discovered in the middle of it; this was somewhat of the shape of an acorn-cup about the size of a walnut, with rough jagged edges, where it had ruptured. The placenta was easily peeled off its attachment inside the broad ligament. The cause of the intestinal obstruction was the pressure of the blood-clot on the intestine which completely blocked the rectum.

A peculiar feature of the case was the presence of a coil of small intestine tightly glued to the fundus of the uterus by an apparently congenital band resembling a mesentery, with the absence of any appendage on the right side.

The abdominal cavity was well washed out with very hot water, temperature 112°, until the fluid came away perfectly clear. The edge of the broad ligament was then sutured to the abdominal wound, and the whole cavity plugged with cyanide gauze; the abdominal incision then closed up. The plugging was removed in forty-eight hours, after which some slightly blood-stained fluid came away. The patient has made an uninterrupted recovery, the wound having healed firmly.

Remarks.—This was a case of primary rupture into the broad ligament, attended by such a large amount of hæmorrhage as to cause complete obstruction of the bowel. The interference (enemata, &c.) necessary to relieve this obstruction, together with the vomiting, which became stercoraceous, caused rupture of the broad ligament, with fresh hæmorrhage into peritoneal cavity, and active operative measures were required to save the patient's life.

Cases of extra-peritoneal hæmatocele rarely reach this state of tension, and generally cure themselves by absorption in time; but on page 32 of Tait's "Lectures on Ectopic Pregnancy" I find he describes a very singular case. In connection with this I should like to mention the pleasure I received in reading Dr. Cullingworth's Bradshaw Lecture, in which he gives credit to Lawson Tait, to whose brilliant surgery we owe all we know of ectopic gestation.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, NOVEMBER 13TH, 1902.

MR. A. W. MAYO ROBSON, a Past-President, in the Chair.

SPECIMENS.

DR. HERBERT SNOW showed a "Uterine Monoma (soft œdematous myoma of Lawson Tait)," a description of which will be found on p. 565.

The **CHAIRMAN** said that Dr. Snow's specimen was undoubtedly of extreme interest; it was very rare to have a combination of these two forms of tumour; in the absence of his notes he would make no assertion he had seen such a combination himself, but he thought he had done so.

MR. BOWREMAN JESSETT did not think that even the soft œdematous myoma was as common as one might suppose from Mr. Lawson Tait's account, but he had seen one or two cases in which a soft myoma, inside the uterus, was associated with other fibroids outside.

DR. MACNAUGHTON-JONES pointed out that the specimen had the appearance of a large fibrous tumour enclosed in a capsule. Degeneration might account for differences in consistency, and, with Dr. Snow's acquiescence, it would be well to refer the specimen for section and further examination.

DR. SNOW, in reply, said that among the many cases in which he had had the advantage of seeing Mr. Jessett operate upon, there had been certainly two or three, in which a large myoma, of the ordinary type, in the cavity of the uterus, had been associated with fibroids elsewhere, and which on a superficial examination looked exactly like his specimen, but were in reality totally different. So far as he was aware his specimen was absolutely unique. The late Mr. Lawson Tait evidently had not met with or heard of one instance in which the soft solitary œdematous myoma, the monoma as he (Dr. Snow) had called it, had been associated with multiple growths of the ordinary myomatous type. He readily concurred in the suggestion made by Dr. Macnaughton-Jones.

DR. MACNAUGHTON-JONES showed (1) An adnexal tumour with the appendix vermiformis. (2) A large blood-cyst of the right ovary with left cystic ovary and hydrosalpinx. These adnexa (1) were removed from a married woman, æt. 29. She had had two children and one miscarriage. The first pregnancy occurred twelve months after marriage, and the second eighteen months later. Shortly after her miscarriage, nine years ago, she was curetted for some recurrent hæmorrhage, and appears to have worn pessaries, on and off, ever since for an assumed retroversion of the uterus. Great pain, however, continued, and for this she was treated with morphia suppositories, having had as many as eight suppositories in the day. The first attacks of pain occurred at the right side, but for several years the pain had been diffused, and for a considerable time she had an offensive vaginal discharge. The catamenia were regular, but very profuse. Her difficulty in walking was due partly to pain, and partly to the feeling of prolapse. There was considerable pain also during defæcation. Constipation followed, and five years since she was operated upon for hæmorrhoids. There was no bladder troubles. On examination, the uterus was found fixed and pushed forwards by a large swelling in Douglas' pouch. The patient was much emaciated, and in a wretched state of health. Her recent medical adviser had enforced rest, stopped the suppositories, and used douches. On opening the abdomen with a comparatively small incision, I found the pelvis in great part occupied by a fixed tumour, evidently distended with fluid. Having enlarged the incision, I succeeded after a short time in isolating the large cyst, and delivering it without rupture of the sac. On delivery of the sac, after section of the pedicle, the fluid, some of which escaped, was found to be blood. The Fallopian tube was adherent and flattened out on the surface of the sac so as to give it the appearance of a hæmatosalpinx, for which, indeed, I mistook it, until subsequent examination proved it to be a blood cyst of the ovary. There was, as you see, a very broad pedicle, which was ligatured in two portions. The adnexa of the left side were found also diseased, a large cystic ovary and a hydrosalpinx. These were removed, the pedicles at both sides were covered, and then the uterus was fixed anteriorly to the fascia, the abdomen being closed with the usual triple sutures. The patient made an admirable recovery.

DR. MACNAUGHTON-JONES said this second specimen illustrated the necessity of careful pathological examination, as, when he removed it, he took it to be a hæmatosalpinx, as also did Mr. Targett when he first saw it, though on more careful examination he found it to be a blood-cyst of the ovary. It was a moot point in cases of the kind, whether it was better to remove the uterus or not. In this instance the uterus was small and perfectly healthy, and he thought the better course was to fix it to the abdominal fascia.

Mr. Charles Ryall, who was present when the first specimen was removed, said the way the appendix was attached, not only to the Fallopian tube, but to the ovary and surrounding parts, was remarkable. He related a case of double pyosalpinx after an attack of pelvic cellulitis and peritonitis, upon which he had himself operated two days previously. When he examined the case he came to the conclusion that the appendix was involved, and at the operation, after separating extensive adhesions, he found a long appendix, distended at its extremity beyond a stricture, lying on an enlarged Fallopian tube containing pus, and adherent to the right cornu of the uterus. The other tube also was affected, and both were removed with the appendix, and the patient was now doing well. It seemed to him more probable that in this instance the appendix was affected after the tubes, than that disease in the right tube, due to infection from the appendix, had afterwards extended to the left one.

Mr. Jessett had met with several instances in which the appendix was involved in adnexal trouble, as indeed he had mentioned in the paper he read before the Society at their last meeting. In one case the appendix was adherent to the fimbriated body, in another to the ovary, in a third to the right tube, while in one, in which there had been a former operation by another surgeon for pyosalpinx, the appendix was found attached to the stump of the old operation. In all such cases he thought that there were symptoms of appendicitis, but, as Dr. Macnaughton-Jones had more than once laid down, it was well to examine the appendix in all operations for adnexal trouble.

The Chairman (Mr. Mayo Robson) had met with at least three cases similar to the one under discussion. He recently removed the appendix attached to the stump of a uterus removed twenty years ago by an eminent London gynæcologist; there had been recurrent attacks of appendicitis during the whole of that time and there were extensive adhesions. In another patient, extremely ill a week after her confinement and supposed to be suffering from puerperal mischief, he found a suppurating appendix, fixed to the tube and ovary, both of which were involved in the abscess; the suppuration extended half-way down the tube, which was firmly glued to the ovary. In all cases where there was pain in the right ovary unaccounted for by prolapse, and tenderness between the anterior spine and the umbilicus, one should examine the appendix, and that was one reason against vaginal operation for adnexal disease. He thought Dr. Macnaughton-Jones had been quite right in not removing the uterus in his second case.

Mr. R. O'Callaghan read notes of a case of

EXTRA-PERITONEAL HÆMATOCELE,

which will be found on page 569.

Dr. Mansell Moullin said that the case was one of extreme interest, as the occurrence of extra-peritoneal hæmatocele had always been debateable, and even Mr. Lawson Tait said any such would be small, and therefore not require operation. It was certainly a very rare event, and one he had never met with in his own experience, and except as a very limited effusion from an intra-ligamentary gestation, he was inclined to doubt its existence. As the patient had recovered, they had no convincing evidence before them.

Mr. Furneaux Jordan concurred that extra-peritoneal hæmatocele was non-existent or extremely rare, and said he had never met with rupture of a tubal pregnancy in the broad ligament, and could not understand how a hæmatocele there could extend over the top of the uterus in the way described.

Dr. Edge referred only to the method of treatment. He had himself in days gone by packed a cavity in the way described, but thought that with the modern advantages of asepsis and technique, it would be better to find and tie the bleeding points, or even the uterine or ovarian arteries, and close the cavity with a continuous suture before closing the abdominal wound.

The Chairman said he sympathised with Mr. O'Callaghan in regard to his case, for in one in which he had made a diagnosis of extra-uterine gestation he was afterwards summoned and found a hæmatocele of the left broad ligament. If there had been in that case a secondary rupture of that broad ligament into the abdominal cavity, such as described by Mr. Lawson Tait, he certainly would have felt justified in opening the abdomen. He thought it was possible to have the exact condition, described by Mr. O'Callaghan, from rupture of the tube into the broad ligament and secondary rupture into the abdominal cavity.

Mr. O'Callaghan, in reply, regretted that the specimen had been accidentally destroyed; obviously he could not bring the broad ligament for their inspection, but he was certain the condition was as he had described it. The profuse hæmorrhage was due to secondary rupture, the extension of the hæmatocele over the fundus of the uterus to the mesenteric band, which he took to be a congenital anomaly; there was neither ovary of the tube on the right side. Mr. Tait did the same operation in the same way, and mentions in his book on "Ectopic Gestation" exactly similar cases, from one of which he removed as much as a quart of blood clot. Mr. O'Callaghan's patient had been for some days in hospital without thought of operation, when signs of fresh hæmorrhage came on; sighing respiration, a pulse of 142 and a temperature of 102° indicated immediate intervention, but in her condition it would not have been wise to prolong the proceedings by attempting to find all the bleeding points. Packing the cavity with cyanide gauze answered very well; she had no rise of temperature after the operation, and made a pleasant and happy recovery.

Mr. Furneaux Jordan showed a cancer of the cervix from a pregnant woman who had had persistent hæmorrhage for eight months, but, until the day before her admission into hospital, had no idea that she was in the family way. She was in the sixth month, but as there was no extension to the broad ligament or to the vaginal wall, he had thought it better to operate at once rather than wait till she might have a living child. He therefore amputated the cervix and then completed the hysterectomy, in the Trendelenburg position, by the abdominal route. The operation was easy, and she made an excellent recovery, and was at present practically well.

In reply to a question from Mr. Jessett, who had entirely endorsed the treatment of the case, Mr. Jordan said that he could not detect any enlargment of the lumbar or sacral glands, nor even felt them at all.

Dr. Edge showed a dermoid cyst removed from a woman six months pregnant; the cyst was adherent to the right hypochondrium and simulated a renal tumour; the pedicle was twisted. Though some of the contents escaped into the abdomen the patient did as well as possible, showing that, though strangulated and threatening in appearance, the cyst itself was not infected. There was no interruption of the pregnancy.

The Chairman congratulated both Mr. Jordan and Dr. Edge on their successful treatment of two cases of exceptional interest.

Dr. Macnaughton-Jones then read a paper on "The Propriety of Conservative Procedures in Abdominal Cœliotomy for Adnexal Disease," illustrated by two specimens, which will be found in our issue for November 19th.

Mr. Furneaux Jordan said that the question proposed was too difficult for a general answer; each case must be judged on its own merits. His own experience was that it was only in exceptional cases that conservative operations on the adnexa of one side, those of the other being incurably diseased, had any chance of success, and that if those of one side only were to be removed the disease must, practically, be limited to that side. It was, however, quite exceptional to meet with lesions warranting removal on one side, without some disease on the other. The condition of the tube was, in his opinion, of more importance than that of the ovary, in regard to conservative measures. He had found patients less anxious to save their appendages than their surgeons.

Mr. Jessett was strongly opposed to what he understood Dr. Macnaughton-Jones to recommend, namely, that if it was necessary to remove one ovary, and the other had one or two cysts in it, both should be taken away. He laid much stress upon the troubles following double oophorectomy, and dissented altogether from Dr. Macnaughton-Jones' dictum that both ovaries should be removed, even if there was only cystic disease in the second one.

Dr. **Macnaugton-Jones**: "Most emphatically that was not my dictum."

Mr. **Mansell Moullin** said the point seemed to be whether, when the appendages were hopelessly diseased on one side, but only partially so on the other, some conservative operation should be performed and the ovary returned. The important influence of the age of the patient had not been alluded to. If she was over forty years, and there was any doubt, he would say take them out at once; but if in a young woman the ovary should be retained. Like all other operators, he had had considerable experience of opening the abdomen a second time for some disease left behind at the first operation; on the last occasion after an interval of only ten weeks, and he had very little confidence in the value of partial operations.

Dr. **Edge** thought that the question should be discussed from two points of view; first, as to the tube and fertility, and secondly, as to the ovary and the possible results of its removal. There was no reason to remove a fairly healthy ovary, even although it were necessary to remove the tube on that side.

Mr. **O'Callaghan** quoted Mr. Lawson Tait's well-known dictum that if in operating for adnexal disease, the appendages on both sides were not removed, a second operation was always required. Simple cysts of the ovary, though found accidentally when the abdomen was opened for some other trouble, were not met with in one case in a hundred of severe adnexal disease.

The **Chairman** thought Mr. Tait's remark referred to gonorrhœal cases, but that the paper did so to adnexal disease in general. For himself he thought that, even in gonorrhœal cases, it was questionable whether it was ever right to remove a healthy ovary because one had to operate for disease elsewhere, and that the Society should not let it be supposed that it at all justified the removal of a healthy ovary on the ground that the other one was diseased.

Dr. **Macnaughton-Jones**, in replying, emphatically repudiated the idea, which was clear from what he had said, that he advocated the removal of such adnexa as Mr. Jessett referred to. He had been most particular to emphasise this. He referred to adnexa in which there was a reasonable doubt of the prudence of any conservative operation, and in which the balance of probability, after any conservative procedure, was in the direction of the need, in the future, for a second operation. He was speaking of partially diseased adnexa, and, as regards the influence of oöphorectomy on the mental side of the woman, the removal of affected adnexa in the instance of the insane was advocated by many most distinguished alienists; a course which was justified by reason of the cures which had followed operation. As to the ablation, under any circumstances, of sound adnexa, this, with the President, he altogether deprecated. Nothing could justify it. He was pleased at the President's emphatic disapproval of the idea. The conclusions he (Dr. Macnaughton-Jones) had summarised in closing his paper referred specially to that class of case in which the adnexa of one side were so diseased as to leave no question of removal, and those of the other so affected as to raise a reasonable doubt of the success of any effort to save them.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Surgical Section.

Meeting held Friday, November 14th, 1902.

Sir **Thomas Myles** read a paper on

LAMINECTOMY FOR PARAPLEGIA DUE TO SPINAL CARIES.

He gave details of two cases, of which one case was successful, and the other experienced no benefit. He discussed the opinions of Sir Victor Horsley and other surgeons, and expressed the opinion that early operation was to be recommended.

Mr. **Doyle** said that he performed laminectomy on a case in 1892. He found pachymeningitis and an abscess in front of cord. Cystitis was also present. The patient had had paraplegia, there was improvement for two or three days after the operation, but subsequently the case did not do well. Most cases would get well if treated by rest and extension.

Dr. **Swan** said one danger from the operation might be a rapid dissemination of the tuberculosis. Cystitis was one of the indications for laminectomy. Some years ago he operated on a case of spinal caries in a boy, in which there was paraplegia and great cystitis, the patient got relief from the bladder symptoms but none from paraplegia. The lumbar region was a bad place for the operation. In most cases paraplegia was caused by disease above the sixth dorsal vertebra. Laminectomy should be done as a routine, but he dissented quite from that. Recovery would come with rest and time extending over say a period of two years. With regard to the operation, he thought the best plan was when the muscles were scraped away first to trephine the bases of the lower spinous processes, and thus get access to the interior of the canal. An objection he had to laminectomy was that the patient was so helpless, could not sit up, nor use his limbs, and the extensive removal of muscles, &c., was a disability not recovered from.

Sir **Thomas Myles**, in reply, said he had only operated on two cases and they were practically experimental. There was a great deal to be said for and against the operation. It was a very serious operation, and a case showing signs of active caries, &c., would not be suitable for operation, but a case with only the paralysis should have the benefit of it. The treatment would be long and too expensive for hospital. The choice of instruments lay between the chisel and mallet, the trephine, or a Giglio saw. The chisel and mallet should be avoided on account of the concussion, &c., and he thought that a Giglio saw could be easily passed with a bent probe, and it might not be necessary to detach the muscles, but merely to turn them back as a kind of flap.

Mr. **Denis Kennedy**, surgeon to the Children's Hospital, read a communication on the "Radical Cure of Hernia in Young Children." He condemned the use of trusses, because they were frequently ineffectual in keeping up a hernia, and because the wearing of them was always associated with a great deal of trouble to the child. He demonstrated the safety with which the operation for radical cure can be carried out, by quoting sixty cases which he had done himself in children under five years old, many of them being under twelve months. In his operations he had three cases of strangulated hernia, all of which recovered. In two cases he met the vermiform appendix in the inguinal canal; in both he resected the appendix, as, on account of their size, he considered they could not with safety be returned to the abdominal cavity. He never had a death resulting from his operation.

Sir **Thomas Myles** thought the operation was a comparatively simple one. The points to be borne in mind were—the necessity for rapidity, arrest of all hæmorrhage, and great care in the administration of the anæsthetic. It was not necessary to carry out any elaborate treatment. Treatment by truss might be successful, but it was merely mechanical and took years to effect what the operator did in so many days. He did not think congenital hernia a common disease.

Mr. **McArdle** said he had operated at all ages from three months to eighty-four years, and he did not see why, in the absence of constitutional disease, the cases should not have the benefit of the radical cure. One complication of the operation he had met with was interference with micturition, and in these cases torsion of the sac had been carried out. In congenital hernias he found no difficulty in separating the cord from the sac if he passed his finger as far as the internal abdominal ring, where the elements of the cord can be felt. Another point was, in the case of a hernia with no posterior sac, such as the cæcum, where you have to push back the cæcum and ligature the portion of the peritoneum which is left behind. With regard to operations on children it was even more essential to split up the anterior wall of the inguinal canal than in the case of adults. All talk about dealing with the sac had no bearing on hernia. In repairing the stratum of the abdominal wall the external oblique had to be brought down to Poupart's ligament, but care must be taken not to displace the cord. In all radical operations we try to imitate Nature, which intended that the cord should lie over the pubis and not pass through a muscular opening. We expose the elements of the cord to intermittent pressure, which should not occur.

Dr. **Taylor** said that first, as to the question of the bladder, he would like to know if it had come into view in exposing the neck of the sac. He had frequently, in drawing the peritoneum upwards, seen the bladder appearing at the internal abdominal ring. He said he was with those who spoke against twisting the sac, and that it should never be employed. He had never had the least difficulty in the treatment of the sac of congenital hernia. He opened up the sac and then the testicle is seen, and he caught each end of it with a pair of clip forceps and put on another pair between, and this enabled him to cut with the scissors along a straight line. There were two different conditions in which the cord was found—one in which the cord lies behind the serous membrane, and one in which the cord is suspended by a fold of serous membrane in which it is floating. If you catch the sac in the middle you can form a serous ridge, and can peel the cord up to the internal abdominal ring. He said it was quite unnecessary to divide the aponeurosis of the external oblique. If you operate early enough you get the inguinal canal in a growing condition, and it accommodates itself to its new position.

Mr. **Tobin** said he differed with Mr. Kennedy on one point, and that was that treatment by truss was, as a rule, unsuccessful. If trusses are continuously applied and worn for one or two years, a radical cure is the rule. It was certainly a very tedious process and hard to carry out; but the fact that radical cure is by obliterating the sac showed that simple pressure was sufficient. Such treatment is out of reach of poor people, but those well-to-do like it, and it avoids the operation. As to the proper treatment for ordinary hernia, he thought that cure by operation was the proper method.

Mr. **Doyle** said he believed that only exceptional cases in children should be operated on. He thought a truss should always be worn for some time after operation.

Dr. **More O'Farrell** said in one case of a child of five months radical cure was performed on one side, and two days afterwards on the other side, circumcision being performed in the meantime, and the child recovered.

Dr. **Houghton** said that radical cure was the right cure and it was very little more dangerous than wearing a truss. The youngest case he had operated on was a child of three weeks. It was a seven months' child, greatly emaciated and very feeble.

Mr. **Lentaigne** said he agreed with Mr. Kennedy that for most hospital patients operation was the best treatment. It was impossible for the mothers in these cases to give the care and attention that the treatment by truss required. Even in the case of wealthy people operations should be allowed much more often than was the case. No complicated operation was necessary. A very simple procedure was sufficient. So long ago as 1884 he operated on an infant, æt. eleven months, for strangulated hernia. In that case the collapsed state of the patient was such that he had barely time to put in one or two sutures, yet he had recently seen that patient perfectly cured of the hernia by that apparently insufficient operation. He had found considerable difficulty in separating the cord from the sac in congenital cases, and he would be glad to try Mr. Taylor's plan next time he met with this difficulty. He had operated on many young children since 1884, and had never had a death, although the first case, already mentioned, had been extremely near to death.

Mr. **Kennedy**, in reply, said that in congenital hernia he had found it impossible to separate the cord from the sac. The elements of the cord formed part and parcel of the sac.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Meeting held Friday, November 7th, 1902.

Mr. Rickard Lloyd, President, in the chair.

Mr. **Alban Doran** read a paper on "Choledochotomy, in a Case of Chronic Jaundice with Cholangetis: Recovery," which will be found under "Clinical Records."

Mr. **L. Bidwell** mentioned the value of Lane's cleft palate needles in suturing deep holes in the common bile-duct. He thought fistulæ from the common bile-duct healed as readily as those from the gall-bladder. He considered that the stones which came away after the operation were probably concealed in the hepatic duct. At any rate, the patient cannot be promised that there will be no recurrence of symptoms. He had not used calcium chloride, as a gauze drain had always controlled hæmorrhage.

Mr. **Percy Paton** mentioned a specimen in the Westminster Hospital Museum, which showed dilated ducts in the liver, containing a large number of stones. As to the comparatively slight importance of a fistula after operation on the common duct, he had seen a case in which such a fistula began to discharge milk given by the mouth, and the patient died of inanition. He advocated the use of adrenalin chloride for controlling bleeding. Jaundice may not be present even when the duct is packed with stones.

Mr. **Pardoe** thought that the severe vomiting five days after operation might be due to cessation of the peristaltic action of the bowels, not uncommon in septic conditions in the abdomen. He had found suprarenal extract very useful during operations upon the urinary bladder.

Dr. **Clemow** asked for any experience of the internal administration of adrenalin. Five-grain doses every two hours had been followed by blanching of the nasal mucous membrane. This suggested the possibility of giving a few doses before such operations as Mr. Doran's.

Mr. **McAdam Eccles** had seen adrenalin of use in the vomiting of blood after gastral enterotomy, and also in a case of severe oozing from the corpus spongiosum after a plastic operation. He used it in 1 in 1,000 solution.

Mr. **Doran**, in reply, said that no doubt recurrence of the trouble was common. Carlsbad salts, however, seemed to help in preventing the formation of calculi. At the time of his operation he had adrenalin ready, but it was not used. Possibly the calcium chloride previously given had been of some use.

Dr. **Frederick J. McCann** read a paper on "Cases Illustrating some of the Septic Complications met with during the Puerperal State." In the first case, the patient had had a raised temperature since the second day, ranging between 101° F. and 103° F. When seen six weeks later, the uterus was found fixed in a mass of exudation, with evidence of softening in Douglas' pouch. The abscess was opened through the posterior vaginal *cul-de-sac*, and was found to be perimetric. The patient recovered. *Case II.*—A primipara, æt. 24; the lochia ceased on the third day; on the tenth day her temperature was 102° F., and she looked ill. The uterus was enlarged, and was found to contain from two to three ounces of pus. The cavity was swabbed with 1 in 4,000 corrosive sublimate solution. The patient recovered. This was an example of puerperal pyometra. *Case III.*—A primipara, æt. 29; on the eighth day she had symptoms of septic absorption; the uterus was swabbed as in the previous case. The patient recovered. The value was here pointed out of swabbing the uterus instead of douching. *Case IV.*—A lady, æt. 32, confined of her sixth child, afterwards developed pyæmia. Three subcutaneous abscesses formed, and she suffered from arthritis, with effusion in knee and ankle-joints. She recovered after a prolonged illness. In such cases the gravity of pulmonary complications was a guide in prognosis. *Case V.*—A primipara, æt. 25, developed parametritis followed by an abscess. The symptoms were delayed for ten months. A swelling was then detected in the right iliac fossa. The abscess was opened and the patient recovered. Such inflammatory deposits may disappear, or may suppurate. Dr. McCann ended by urging that labours should be conducted as carefully as modern surgical operations, and that as few vaginal examinations as possible should be made.

Mr. E. Lloyd thought strychnia of great service in such septic cases, its cumulative action, however, being remembered. Oxygen also was likely to be beneficial. As regards the causes of such septic conditions, the environment of the patient, or previous pathological conditions should be remembered.

Dr. Mansell Moullin divided septic infections into local and general varieties. In the local, the patient generally recovers, but the condition is a fertile source of gynæcological troubles. In general sepsis, the condition is either one of general septic peritonitis, or pyæmic in nature. In either case, the treatment is not very satisfactory. Dr. Moullin condemned the use of the curette in septic cases. He noted the fact that auto-infection is undoubtedly the cause of some cases of puerperal sepsis.

Dr. Chambers remarked on appendicitis as one of the obscure complications of the puerperium.

Dr. Clemow said that labour is a physiological process, and ought practically to be unaccompanied by rise of temperature. If, however, the lochia became offensive, careful douching was necessary. The douche-can should not be raised more than two feet above the patient's body. He advocated douches of 1 in 2,000 corrosive sublimate solution, or, better still, of chinosol.

Dr. Musson pleaded for greater power for the sanitary authority in regulating the midwives.

Dr. Drummond Robinson uttered a word of warning against the employment of the curette in the removal of portions of retained placenta. It might fail to remove the placenta, or it might give rise to septic infection. He also called attention to the frequency of cases of mild septic infection after labour, or miscarriage, the results of which only show themselves, perhaps, some time afterwards, in pelvic pains, &c.

Dr. McCann replied.

THE LARYNGOLOGICAL SOCIETY OF LONDON.

A meeting of this Society was held at 20, Hanover Square, W., on Friday, November 7th, the President, Mr. E. Cresswell Baber, being in the chair.

Mr. P. de Santi showed a case of tertiary syphilis of the larynx in a man, æt. 26. He had treated the patient four years previously for secondary syphilis, which cleared up. The patient returned in October, 1902, with hoarseness, some difficulty of breathing and slight pain. On examination, besides the signs of chronic laryngitis, there was a large, firm outgrowth from the left cord and considerable swelling in the interarytenoid space. For this condition, the patient had been under treatment for some time at the Throat Hospital. Mr. de Santi raised the question as to whether it would be advisable to perform thyrotomy and remove the diseased interlaryngeal area. Dr. FitzGerald Powell, who had treated the case at the Throat Hospital, was of opinion that the growth was pachydermatous in nature.

Mr. de Santi also showed a case of growth of the left vocal cord in which the diagnosis rested between tuberculosis and pachydermia.

The President showed a case of extensive fenestration of the anterior pillars of the fauces in a boy, æt. 13, and raised the question as to whether it was the result of ulceration or congenital in origin.

Sir Felix Semon thought that these cases were congenital, otherwise he saw no reason why the condition should be so often absolutely symmetrical.

Mr. C. A. Parker showed a case of double abductor paralysis with swelling of the arytenoids in a man, æt. 38. There was some dysphagia and some impairment of resonance of the right apex. But two examinations of the sputa had revealed no tubercle bacilli. There was a varying inequality of the pupils, but no other sign of nervous lesion. A large bougie could be passed, but seemed somewhat gripped about the level of the cricoid.

Mr. R. Luke showed a case of removal of the epiglottis for tuberculous disease in a man, æt. 35. The operation was undertaken for the relief of dysphagia, and had proved entirely successful.

Dr. J. Donelan showed a case of pedunculated laryngeal growth, probably dating from birth, in a boy, æt. 15. The presence of these growths had apparently caused stunted growth and depreciation of general health.

Dr. Scanes Spicer showed a readily-improvised working model to demonstrate the air-channels and currents in the nasal cavities in normal and impeded respiration. The results of experiments with this apparatus confimed those of Paulsen and Franke on the cadaver, and Parker's on the living subject.

Mr. F. Hunter Tod showed a case of left antral empyema followed by abscess of the hard palate and of the septum nasi, all of which were secondary to a severe attack of toothache. Mr. Hunter Tod also showed a case of double antral and frontal sinus disease in which the left side had been cured by radical operation. He now raised the question as to whether the right side should be similarly treated.

Sir Felix Semon showed a case of obscure lardaceous-looking variable infiltration of the uvula, soft palate, and right arytenoid in a lady. On examination the uvula and the adjacent parts of the soft palate were seen to be considerably infiltrated and smooth to sight and touch, and of a peculiar yellowish colour, resembling the appearance of a lardaceous kidney. The right arytenoid presented a similar appearance. There was some fulling on pressure about the external malleoli, but the urine had been found perfectly normal. The patient had been treated with arsenic and iron, and the local condition had somewhat improved. Sir Felix Semon had seen two similar cases, but did not think the condition had ever been described. He was unable to make any suggestion as regards their pathology.

Sir Felix Semon also showed a case of ulceration of the left tonsil, with acute and considerable enlargement of numerous cervical glands on both sides of the neck, in a man, æt. 70. The ulceration was apparently sequel to an attack of acute peritonsillitis, which had occurred six weeks previously. The patient's age and the implication of the cervical glands pointed to malignancy, but a piece had been removed for microscopical examination, and Mr. Shallock reported that he regarded the tissue as inflammatory, rapidly-growing granulation tissue.

Dr. FitzGerald Powell showed a case of cyst of the epiglottis which practically caused no symptoms.

Dr. A. H. Burt showed a case of epithelioma of the tongue in a single woman, æt. 24.

Dr. Furness Potter showed a case of recurrent ulceration of the pharynx and larynx in a woman, æt. 56, which he thought to be herpetic.

Dr. H. Tilley showed a case of vascular nasopharyngeal fibroma of extensive origin. Several attempts had been made to remove this growth, but without permanent success. Finally it was successfully and completely removed by a combined operation through the soft and hard palates and extensive removal of the anterior wall of the left superior maxillary bone.

Dr. H. L. Lack showed a case of complete adhesion of the soft palate to the posterior wall of the pharynx.

Mr. C. A. Parker showed a case of persistent epistaxis in a man, æt. 42, which had been going on for eighteen months, and had completely disabled the patient from work.

Dr. J. Dundas Grant showed a case of paralysis of the abductors of the vocal cords and of the palatal muscles, with slight paresis of the tongue, in a man, æt. 25, which he considered due in all probability to a lesion of the vagus nerves in or near the medulla oblongata.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD THURSDAY, NOVEMBER 6TH, 1902.

The President, Dr. JOHN ROBERTSON, in the Chair.

DR. G. WILKINSON showed (1) a case of palliative gastro-enterostomy for malignant obstruction of the pylorus. The patient's general condition had improved since the operation, two months previously. (2) A case of ruptured gastric ulcer, operated on fourteen hours after rupture. (3) A case of arterio-venous communication. The patient, a man, æt. 23, was stabbed with a penknife in the left thigh, near the apex of Scarpa's triangle, five months previously. There was free hæmorrhage at the time, which was controlled by firm bandaging and elevation of the limb. About a fortnight later a marked thrill and loud rough bruit were found in the region of the wound. The circulation through the limb was not interfered with, nor was there any œdema or wasting of the muscles. No definite swelling could be detected in the region of the wound. The thrill and bruit were conducted upwards along the vessels more distinctly than downwards. The absence of symptoms was explained on the hypothesis that a narrow channel of communication between the superficial femoral artery and vein existed, passing upwards from artery to vein, and so sending a jet of blood into the vein in the direction of the venous flow, and accelerating rather than retarding the stream in the vein. The thrill was gradually becoming less marked. No operative treatment was proposed.

Mr. **WILKINSON** also read notes of a case in which he had enucleated five large hydatid cysts from the liver, afterwards sewing up the fibrous capsules without drainage. The case made a good recovery.

Mr. **R. FAVELL** showed a large fibroid polypus of the uterus, and related a case of Cæsarean section for obstructed labour by an ovarian dermoid.

Dr. **ARTHUR HALL** showed (1) an extensive case of lupus affecting the greater part of the left arm; (2) case of erythema induration of Bazin, showing the characteristic scars: (3) a specimen of malignant intrathoracic growth, with a large thrombus filling up part of the superior vena cava. The patient had marked œdema of the right arm, face and chest.

Dr. **WILKINSON** read a short communication, entitled

A NOTE ON THE TREATMENT OF INTUSSUSCEPTION.

His remarks were based on four successive cases, all of which had been reduced by water syphonage. In one case the symptoms had lasted three days before the patient's admission to hospital. In another the intussusception was felt by the finger just inside the anus. He concluded that the method of syphon pressure was not deserving of the censure which many modern writers had bestowed upon it.

SOCIETY OF ANÆSTHETISTS.

The first ordinary meeting of the Tenth Session was held on Friday, November 7th, 1902, the President, Mr. WALTER TYRRELL, in the chair.

Before commencing the proceedings the President read a newspaper report of a case of death immediately following the administration of nitrous oxide gas; it appeared that the patient made a very slow recovery from the gas, and strong ammonia was therefore held to his nostrils. The post-mortem report showed acute congestion of the mucous membrane of the air passages The President, having had the report of the case sent to him anonymously with the suggestion that the ammonia had caused the congestion, and therefore the death of the patient, promised to inquire into the case and again bring it before the Society.

The **PRESIDENT** then called upon Dr. Starling, of Tunbridge Wells, to read the report of his case of Reflex Inhibition or the Heart during the Administration of Ether, in which manual compression of the heart was successful in restoring the circulation.

Dr. **STARLING** said that the patient was a male, æt. 65. The usual preparations were made for abdominal section for adhesions about the colon, and ether given by a Hewitt's large-bore inhaler preceded by gas. The patient was of the thin nervous type, and had a muffled bruit of the first sound of the apex; was otherwise healthy. The induction of anæsthesia was easy and normal. The appendix being found unhealthy was removed, then the pulse immediately began to flag; the respirations, which had been shallow, were not affected; more ether was given, but during the trimming of the stump both pulse and respiration stopped together. Artificial respiration by compression of the chest was started at once, without any effect; the surgeon (Mr. Lane) introduced his hand through the abdominal incision and felt the heart through the diaphragm—it was quite motionless; he gave it a squeeze or two, and felt it restart beating, but, as the voluntary respirations were still suspended, artificial respiration was continued, and other restorative measures adopted; the artificial respiration had to be continued for about twelve minutes, when natural respiration recommenced with a long sighing inspiration. The operation was completed without any more anæsthetic, there being slight movement while the skin sutures were being put in. Except a little pain about the diaphragm for two days he made a good convalescence. Dr. Starling said he had brought this case before the Society not only because of the successful treatment by direct stimulation of the heart, but because he thought it was somewhat unusual for a patient fairly under the influence of ether, to suffer to such an extent from reflex inhibition: and further, though the stimulus to the heart was enough to restart it, yet the steady persistence with artificial respiration was essential to the recovery.

Mr. **WILLET** said that he did not believe that patients suffered from reflex inhibition as a result of a light anæsthesia, and he did not think that it was dangerous on that account to keep patients lightly narcotised.

Dr. **BUXTON** then read reports of three cases of great interest in which he had had to administer chloroform for laminectomy for spinal injuries, in which, as the result of injury, the ordinary muscles of respiration, with the exception of the diaphragm, were paralysed. In these cases he had been obliged to resort to perflation in order to restore suspended respiration, since the ordinary methods of artificial respiration were inadmissible owing to the injury. These cases gave rise to some little discussion and Dr. Buxton replied to questions asked thereon.

Mr. **HILLIARD** read notes of a case of cerebral hæmorrhage during the administration of chloroform, the patient dying forty-eight hours after the operation.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, Nov. 23rd, 1902.

CHLORIDE OF CALCIUM.

THE great hæmostatic value of chloride of calcium administered internally has not yet been entirely accepted by practitioners, and yet it can nearly in all cases be depended upon. Dr. Bertignon took recently as the subject of his *these* this drug, and furnished a series of cases in which chloride of calcium was proved to be an excellent hæmostatic.

It succeeded where perchloride of iron, antipyrin, ergotin, and hot injections failed. It is indicated in hæmorrhages of every kind, and in all maladies presenting hæmorrhagic complications. Hæmatemesis, hæmaturia, enterorrhagia, and metrorrhagia, are arrested rapidly by $CaCl^2$. M. Bertignon cites the case of a patient suffering from acute general purpura cured, where ergotine, perchloride of iron, citric acid, lemonade, &c., were tried without success.

Germain Sée, speaking on the subject, said that of all the coagulating solutions known, chloride of calcium was the most easily borne by the stomach. In more than one instance at the hospital had he seen it succeed when prescribed for grave hæmatemesis.

For intestinal hæmorrhage complicating a case of typhoid fever enemas of a drachm of the salt and half a drachm given by the mouth, with a little opium, have given very good results. It is especially indicated in hæmophylia.

The best formula, according to Dr. Bertignon, is:—

Chloride of calcium (crystallised), ʒj;
Syrup of opium, ʒiij;
Water, ℥iv.

To be taken every twenty-four hours and renewed as long as the hæmorrhage lasts.

Infantile Mortality.

Dr. Variol, two days ago, read a paper before the Committee on Depopulation, interesting with regard to infantile mortality.

The malady, he said, which caused the greatest number of victims in Paris was tuberculosis in all its forms. Out of 5,500 deaths, 2,700 were due to that affection. Infectious diseases, and of these the most dangerous measles and whooping cough, carry off 1,500 children yearly. Diphtheria and small-pox, thanks to serum and vaccine, are kept well under control, while typhoid fever was becoming every day more anodine by reason of the good water supply, but there existed a plague which it seemed impossible to check; he referred to hereditary syphilis.

The unfortunate children born of contaminated parents are condemned as soon as they see the light. Of 62,000 pregnancies yearly there are 9,000 products of conception still-born, the remainder perish in the proportion of 60 to 80 per cent. One half of the children of Paris are born and die in charge of the Administration of Public Assistance. The infantile mortality in the hospitals is formidable (5,500 yearly). This mortality might be considerably reduced if the hospitals had resources indispensable for the refection of the wards which, for the greater part, were of revolting insalubrity. Some of the hospitals have not been repaired since their formation. That of Les Enfants-Malades, for instance, which dates from the end of the eighteenth century, has received but little or no modification for many years.

Quadruplets.

The birth of quadruplets is reported to have taken place a few days since in Paris. The first child was of the male sex, and was still-born; the second was a girl, and the two last were girls and joined together above the thigh exactly in the same way as the recent Hindoo twins Radica and Doodica. A considerable number of cases of quadruplets are to be found scattered through medical literature. In Ireland such plural births are comparatively few; amongst 240,000 women who were delivered in the Rotunda Lying-in Hospital, from its foundation to 1900, only one case of quadruplets is recorded.

Germany.

[FROM OUR OWN CORRESPONDENT.]

Berlin, November 22nd, 1902.

At the Hufeland Society, Dr. Binz, of Bonn, discussed the status of

Alcohol as a Medicine.

He took up the position that for the sound, well-nourished man alcohol was unnecessary, and that the immoderate use of it was harmful for the individual and even for whole nations.

The question was different, however, when alcohol was considered as a medicine. Here it must be considered that it was an active remedy, and both its stimulating and its nourishing properties were to be considered.

In recent times, the well-known symptoms of excitement of alcoholic drunkenness have been looked upon as due to partial inhibition of certain regulating centres in the cerebral cortex, which under normal conditions prevent disordered movements and mental processes. As the measurement of psychical action resulting from measured doses of alcohol was difficult to carry out, the respiratory centre and the respiratory organs were turned to. The experiments which were begun more than twenty years ago were for the purpose of determining how respiration was influenced by doses of alcohol. It was shown that respiration was more than doubled by the drug, a fact which must be looked upon as an undoubted condition of irritation.

In a fasting condition alcohol acts more powerfully. Here the whole respiratory apparatus is placed in a state of activity by moderate doses of alcohol. Under normal circumstances the respiratory curve drops down below the normal curve. When no exhaustion is present we see a slight heightening of the respiratory curve, and this falls again in correspondence with the time of the day. In exhausted individuals the respiratory activity is considerably increased under the influence of alcohol. (The different experiments were carefully detailed).

As a result of his experiments the conclusions were: —Alcohol in moderate doses increases the respiratory activity in a moderate degree. The same doses increase this activity more markedly when the persons experimented on were fasting. The increase persisted even when the persons experimented on were sleeping or sleepy from the alcohol given. The presence of bouquet in wine further increases the activity.

As regarded the nutrient action of alcohol, similar experiments were made on people who had previously been brought into a state of equilibrium as regarded nitrogen, and it was found that an increase of nitrogenous disassimilation took place.

Cocainisation of the Spinal Cord.

This method of producing anæsthesia of the lower extremities has been before the profession of late, and was recently tried on sixty persons in the Breslau Clinik, every possible precaution being taken against infection. A good deal of pain was felt when the needle penetrated the dura mater, so that almost all the patients flinched at this point.

After the injection, or after the onset of analgesia, a number of unpleasant bye-effects were observed. Besides slight and transient pallor, nausea and inclination to vomit came on, sometimes culminating in violent vomiting, and very profuse sweating. Further, general restlessness, distress, and a feeling of tightness were felt, as well as intense tremor of the whole body or of the lower extremities. Several times patients felt a tickling or dryness in the throat. There was collapse in two cases. After operation the patients were, of course, put to bed. In a large number of them the action of the cocaine ceased with the analgesia. But in a large number after-effects of the most varied kinds were observed, some exceedingly disagreeable, if not actually dangerous to life. From simple loss of appetite and nausea lasting as long as three days, there were all degrees, up to vomiting lasting two days. Pain in the sacrum, back and neck were very frequently observed. Very frequently violent headache came on lasting several days. Lastly, there were abnormal weakness and sleeplessness for some days and singing in the ears. In a few cases there was slight retention of urine and some rise of temperature, but not above 38·8° C.

In consequence of these disagreeable bye-effects this method of producing analgesia has been given up in Mikulicz's Clinik, and more particularly so since ether has been employed in place of chloroform.

In other reports on the employment of cocaine by Bier unpleasant effects, sometimes lasting for several days, are noted. Nearly constant headache and a feeling of formication, as well as weakness of the legs, are observed, sometimes trembling.

In a young man suffering from sciatica a 2 per cent. solution was injected, and the above-mentioned symptoms appeared; the temperature rose to 38·9° C. and returned to normal in thirty-six hours. The analgesic effect was practically nil. After disappearance of all symptoms a 2 per cent. solution was again injected, but this time it was carefully sterilised. After a few hours a violent rigor came on, the temperature rose to 40·5° C., and there were violent pains in head and neck, restlessness, irregularity of pulse, and vomiting. The temperature subsequently rose to 40·8° C. Lumbar puncture was now made. The cerebro-spinal fluid was cloudy, and microscopical examination showed numerous polynuclear leucocytes. Albumin over 2 per cent. Bacteriological examination revealed nothing. The inflammatory process was therefore of a toxic and not of a septic nature.

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, November 22nd, 1902.

Rontgen Posology.

Holzknecht raised a question which has frequently been asked, viz., What is the strength that should be used when treating with this radiant and powerful agent? Teleky, he said, had given us different intensities for the treatment of skin diseases. Riehl had devised a colour scale, while Schiff had affirmed that the clinical aspect of the case was the safest guide. This assertion Schiff has now modified, and he now affirms that individual idiosyncrasy and the varying resistance of the organism must be the physician's guide.

Teleky relates a few cases in which he had applied the rays for many months, in one case for a year, for epilation, after which telangiectasis appeared. He now asks himself if the latter untoward circumstance arose from the method of application or the strength employed. Freund is confident this injurious effect will not arise if the operator abandons the use of the rays immediately he observes the slightest trace of dermatitis. Ehrmann discussed the very great difference in individuals in their power to withstand the untoward effects; some suffered severely, while others remained unaffected by the same ray. This, Holzknecht observed, was as true of morphia as it was in the Röntgen rays.

Psychiatrics and Neurology.

The Society for Psychiatry had been asked to inaugurate a course of lectures on their particular subject, which is a new departure in the scholastic training connected with the Vienna School. The first of the course was given last week, at which 200 post-graduates were present, and before leaving 110 inscribed their names as members for the whole course. Nothnagel's theatre was selected for the first meeting, but, presuming it would be too large, a smaller room had been secured for the succeeding lectures; the surprisingly large number in attendance, however, has induced the society to arrange with Prof. Nothnagel for the use of the theatre. The lecturer commenced with the initial stage of progressive paralysis, and by appropriate examples made his address both instructive and interesting.

Sulphuric Acid Burns.

At the "Gesellschaft der Aerzte" Haberer brought forward a patient, æt. 28, with a very large part of the face destroyed from contact with sulphuric acid. The skin was almost absent on the whole of the right side of the face and part of the left, which presented a large granulating surface. The right ear and eye were obliterated, as well as the right eyelids, and the left side of the nose was also partially destroyed. In consequence of the secondary changes that had taken place the sight was so much impaired that the patient could not count or distinguish coins between the fingers. The only relief possible for the patient was a large plastic operation.

Concretio Pericardii.

Ehrmann showed photographs and skiagrams of a patient whom he had treated for thirteen years for scrofula. In 1879 the patient suffered from deposit on the pericardium, and in 1885 glandular abscesses in the right supra-clavicular fossa, presumably due to scrofula, which, however, promptly yielded to anti-syphilitic medication and iodoform dressings. This was soon followed by pseudoarthrosis in the upper part of the right arm reaching down to its middle third, which probably arose from central gumma of the bones. The skiagrams showed the ends of the bones to be fan-shaped. A closer investigation of the patient's early life proved the syphilitic presumption to be correct.

The Operating Theatres.

GUY'S HOSPITAL.

Two Operations for Recurring Attacks of Jaundice.—Mr. Arbuthnot Lane operated on a woman, æt. 35, who had for some years suffered from recurring attacks of abdominal pain and jaundice, accompanied by tenderness in the region of the gall-bladder. A hard rounded lump could be felt in the edge of the liver, which seemed to be the gall-bladder filled with stones, while below the liver and on a plane considerably behind its outer margin another hard lump could be felt, which was even more tender than the other; it seemed as if this might be a stone in the common bile duct, but about this there was considerable doubt. On opening the abdomen the gall-bladder, which was about the size and shape of a thumb, was found to have become detached from the under surface of the liver, from which it hung by its duct and a loose mesentery; it was filled with stones and was very hard. The mass in the liver was dense, white, and hard, and extended from the edge of the liver upwards for nearly an inch and a-half; it bulged beyond the upper and lower surfaces of the liver and simulated a secondary growth in appearance. It was very difficult to say whether it was a secondary growth or a cavity in the liver distended with gall-stones; in either case it was clear that its free removal was the wisest course that could be adopted under the circumstances, consequently a wedge which included the lump and the adjoining portion of liver was excised. and the incised edges were brought carefully together by sutures. The large gall-bladder was found to communicate at its junction with its duct with the cavity in the liver which was clearly inflammatory in origin, suppuration having probably taken place about an obstructing stone. The diseased gall-bladder and its duct were carefully removed, and a gauze drain was left in the wound, which was closed.

The same surgeon operated on a man, æt. 21, for recurring attacks of pain and tenderness in the abdomen, which had recently been accompanied by the presence of jaundice. During the attacks the liver became enlarged but at the time of the operation it was practically of a normal size. The gall-bladder could be felt in its proper position; it was not enlarged, but was hard and tender, the tenderness being a marked feature; nothing could be felt in the common bile duct. There was no jaundice at the time of operation; the urine and fæces were also normal. The abdomen was opened, and the gall-bladder was found to be filled with small stones and its wall to be very much inflamed and thickened, and attached to the surrounding structures. The adhesions were carefully divided and removed, and an attempt was made to excise the gall-bladder and the cystic duct. On separating the gall-bladder from the under surface of the liver a cavity, about the size of a walnut, containing mucus and gall-stones was found in the under surface of the liver, which was evidently at one time an abscess cavity; it communicated with the interior of the gall-bladder through an opening in its wall. The gall-bladder and cystic duct were excised. The cavity in the liver was plugged with a gauze drain, and the abdominal wall was sutured except at the point of emergence of the gauze drain.

CHELSEA HOSPITAL FOR WOMEN.

Conservative Operation for Diseased Appendages.—Dr. Arthur Giles operated on a woman, æt. 23, who had been married about a year. She had been under treatment some time in the out-patients' department on account of retroversion of the uterus with fixation. As the condition did not yield to minor measures the patient was admitted with a view to separation of adhesions and ventro-fixation. The uterine fundus was found firmly fixed in the pouch of Douglas, and was first freed by separating the adhesions. On examining the uterine appendages it was found that both ovaries contained several small cysts, and both Fallopian tubes showed a remarkable appearance; in each case the tube had become divided into two portions, the fimbriated extremity having become separated from the rest of the tube at a point about two inches from the uterine end of the tube. The proximal part of the tube presented almost exactly the appearance of a vermiform appendix, its free extremity being smooth and rounded; the short portion representing the fimbriated extremity was somewhat atrophied. The patient before operation had expressed a strong desire that the ovaries should be saved if possible. The small cysts in the ovaries were punctured and an artificial ostium was made at the end of each tube by opening the canal of the tube and by uniting the serous and mucous cut edges with one or two fine sutures. The uterus was then slung up to the anterior abdominal wall by two silkworm gut sutures and the abdominal wound closed in the usual way in three layers. Dr. Giles said that the etiology of the condition was of great interest; the occlusion of the tubes practically amounted to a spontaneous resection, as if the tubes had been ligatured in continuity, and subsequently divided at the point of ligature. He thought the only way in which this could be supposed to have happened was strangulation of the tubes by bands of adhesion due to a very old standing peritonitis, which had also involved the uterus, and led to the adhesion of the fundus to the pelvic floor. He was led to adopt a conservative procedure, he pointed out, not only in deference to the express wishes of the patient, but also because, in the absence of any recent inflammatory condition, the case appeared to him eminently suitable for conservative treatment. Puncture of the small cysts in the ovary was generally sufficient, and he had never met with a case in which an ovarian cystoma developed out of an ovary so treated. It appeared to him somewhat doubtful whether the restoration of the patency of the tubes would be followed by pregnancy, but cases had been recorded in which conception had occurred under much less favourable conditions than obtained in this case, and he had therefore felt that it was worth while making the attempt. He believed that conservative operations on the uterine appendages might be performed with advantage in many cases in which at first sight the choice would seem to lie between the two extremes of ablation of the appendages and doing nothing at all. Palmer Dudley, of New York, and others have, he pointed out, done some excellent work in this field, and some of the results have quite exceeded their expectations. Naturally, he said, such conservative procedures must have definite limitations; they were out of the question in acute inflammatory conditions and in cases in which the appendages were considerably disorganised by disease. He drew attention to the way in which the artificial ostium had been made: in the case of one tube the end of it was simply cut off transversely, making a terminal opening; with the other tube he had slit the distal end for about half an inch, and then united the serous and mucous cut edges of each border; this gave an elongated ostium which approximated nearer to the normal condition, and was therefore, he thought, the better procedure. The after history of the case would, he considered, of course be a matter of great interest.

The patient made an uneventful convalescence, and left the hospital seventeen days after operation.

The annual meeting of the City Hospital for Diseases of the Skin will be held at the Mansion House, Dublin, on Thursday. the 27th inst., at 4 p.m. Sir Charles Cameron, C.B., M.D., will preside.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 26, 1902.

THE COMMONWEALTH OF SCIENCE.

The love of war, in the very nature of things, forms one of the strongest characteristics of the strongest nations of the world. Not only is it necessary for self-preservation, but it must also have previously played an essential part in the building up of the national edifice. In the modern comity of nations it has led to the formation of vast standing armies and navies, and to the creation of an armed neutrality which in itself is many times more costly than the administration of the whole government of former days. At no period of the world's history has the spirit of international strife and jealousy been more pronounced or more threatening and complex in its many ramifications. Under such circumstances the recognition of some common interest among a host of conflicting issues is a welcome harbinger of the future millennium of peace that has from the dawn of history filled the minds of philosophers. It may be that the fulfilment of the dream may depend on science, which has already conferred so many benefits upon mankind. So far modern discovery appears to have stayed the progress of peace by placing fresh weapons in the hands of Mars. For all that, there is much to be said in favour of the view that the rapid development of scientific warfare tends to render war more and more impossible. Be that as it may, there can be no doubt that science will benefit the world far more by the conservation than by the destruction of life. In that way the triumphs of scientific medicine provide a strong and solid basis of common value to every nation upon the face of the earth. The Röntgen rays were discovered in Austria, and a year later they are being applied in every part of the world. The tubercle bacillus demonstrated at Berlin straightway becomes the property of all civilised nations. The principles of aseptic surgery being announced in Great Britain forthwith revolutionise the practice of surgeons in all Christendom. The fact is, that in scientific medicine there is rivalry without jealousy, and the fruits of discovery belong in the truest and widest sense to all mankind. This gospel was clearly in the mind of Lord Lister when addressing a meeting called recently in London with the object of contributing to the memorial to be raised to the late Professor Virchow. The labours of that distinguished man of science belong essentially to the commonwealth of nations, and it is fitting that a monument to his genius should be cosmopolitan in its foundation. Indeed, as Lord Lister hinted, it would be appropriate were we or any other nation to erect our own statue to Virchow, who is the world's benefactor. Precisely the same line of reasoning applies to that great and original genius, Pasteur, and, if it be permitted to say so, to Lister himself. The struggles for survival amongst the peoples of the world stand recorded in many a sordid page of history, redeemed, it is true, here and there by noble and stirring achievements. The struggles of science, on the other hand, are still, as it were, the mere skirmishing of outposts, but their success has been such as to inspire confidence in the approach of an overwhelming conquest at no distant future. Meanwhile, it is pleasant to find that the self-sacrificing and devoted labours of workers in the field of scientific medicine are obtaining in some measure the meed of universal approbation.

THE MOTOR-CAR AND THE MEDICAL PROFESSION.

The motor-car has come to stay. In spite of the grumbles of motorphobists it is rich in possibilities of health and happiness. The introduction of any new pleasure is almost inevitably accompanied by opportunities for the development of physical defects, and every fresh occupation may speedily lead to associated morbid states. But such can be accounted for as defects of virtues. Certainly the advantages of the automobile far outweigh its drawbacks. And the medical profession may well welcome its advent on many grounds. That enthusiastic octogenarian, Sir Henry Thompson, whose recollection goes back to the good old coaching days, when railways were indeed rarities, has recently issued a charming little volume of praise for the motor-car, and much sensible advice regarding its nature, use and management. For professional work, especially in certain districts, the automobile furnishes medical men with a rapid and convenient means of locomotion, saving time and in the near future, it may be hoped also saving money. No doubt in some country towns, and especially in hunting districts, medical men will be deterred by local prejudice, but, generally speaking, the automobile will simplify travelling for professional purposes. And we venture to think it will not be long before many of our large hospitals, and especially such institutions as sanatoria for consumptives, realise that in the automobile they have a ready means of providing health-restoring measures for their patients. At the present time in connection with many asylums and establishments for the crippled, blind, or otherwise deficient, occasional drives are provided at considerable expense, and necessarily very limited in application. The Boards of Management of such places should consider the opportunities which the automobile places at their disposal. But not only as a pleasurable means of travel for the healthy, and a convenient method for conveying the injured, sick, and convalescent, the automobile may be welcomed as assisting in securing a more sanitary condition of our streets. The accumulation of horsedung and the decomposition of equine urinary secretion, although custom has more or less taught us to regard such conditions as quite fit and proper, afford nevertheless hygienic errors which a more enlightened age will wonder we could ever tolerate, and that certainly play a part in the impairment of health, and doubtless, at least to some extent, are instrumental in the actual initiation of disease. No one can calmly consider the advent of the automobile without recognising that it may be of much service in the prevention of morbid states and useful in assisting in the restoration of the diseased. No doubt for long the farmer and other constitutional grumblers will protest against the motor-car " huzzin' an' maäzin' the blessed roäds wi' the devil's oän teäm," but doctors, sanitarians, and sufferers may well accord the new steed a warm welcome.

THE CONFLICT OF MEDICAL TESTIMONY.

We published last week an article dealing with what may be called the etiology of conflicting medical testimony, by Mr. Ormsby, the president of the Royal College of Surgeons in Ireland. The subject is one which invites discussion, not only because this divergence of opinion places the medical profession as a whole, and medical experts in particular, in an unfavourable light before the public, but also because, by studying the cause of these contradictory opinions, it may be found possible, if not to obviate them, at any rate to reduce them to a minimum. To begin with, the medical assessor who visits the plaintiff on behalf of a defendant company or person and the plaintiff's medical adviser in reality inspect two different men. The frame of mind and outward aspect of the individual present extraordinary differences according to the circumstances under which he is interviewed. To the one he willingly confides everything that can assist him in a diagnosis, to the other he as willingly hides everything that can be concealed without positive *suppressio veri*. If both medical examiners could inspect the patient under precisely similar conditions no doubt one great factor in the production of divergent opinions would be obviated. Although Mr. Ormsby suggests sundry means of minimising this source of error, it is probably inherent to the present system of pitting medical witnesses one against the other, instead of appointing a medical assessor on behalf of the court, who would presumably be absolutely neutral as between the parties. Admitting, with the author, that certain disadvantages attend the practice of the expert examination being made in the presence of the ordinary medical adviser of the plaintiff, it is unquestionable that the advantages outweigh the drawbacks. We can hardly conceive of an examination carefully carried out by two medical men in each other's presence which would leave room for any difference of opinion between them as to the reality of the existence of certain signs and symptoms. The only possibility of disagreement between them lies in the importance to be attributed to the subjective symptoms, and, after all, this is not a point as to which medical evidence can be reasonably expected to throw any light. Their significance turns solely and wholly on the credibility of the patient himself, and this is a matter which the jury must decide. As the author points out, it is exceptional for any serious difference of opinion to become manifest in court between practitioners or between a practitioner and an expert. It becomes disagreeable when two or more experts are pitted against each other, each straining a point in favour of the party in whose interests he has been retained. In all probability this would be avoided if the same line of conduct were followed, viz., that no examination of the patient should take place save in presence of ALL the medical witnesses in the case. We repeat that it must always be possible to agree as to the existence or otherwise of objective lesions. As to the significance to be attached to these lesions, in other words the gravity or otherwise of the prognosis, of course there are two ways of looking at it. There is the optimistic and the pessimistic way of considering the future. No fault can be found with medical witnesses in respect of any conflict of opinion in this connection. Medical men are not prophets by nature or by training, and only a limited confidence can be accorded to their views when they leave the region of established, observed fact and launch out into what is mere hypothesis. Nevertheless, it is of assistance to an intelligent jury—would that there were more of them—to know the best and the worst prospects of a patient under given circumstances.

Notes on Current Topics.

Modern Sanitary Aims.

The simple trust of the early public health reformers, such as Parkes and Farr, in a great sanitary future was not unfounded, if we may judge of the fruit borne by the trees which were in great part planted by their energy and wisdom. The mortality rates of the United Kingdom have been steadily reduced in every decennial period for the last fifty years, but, in spite of the enormous improvement in that direction, there still remains a broad margin of preventible and unnecessary disease and death among the community. Progress is slow, inasmuch as the practical administration of advanced hygienic measures is vested in the hands of the people whom it is proverbially hard to move to enthusiasm over matters of reforms. The chief sanitary aims of our municipalities are curiously alike. The wants of the one are the wants of the many. Bristol may be taken as a good type of a modern town progressive from the public health point of view. The objects of its Health Committee are formally announced as embracing, first and foremost, the erection of ample infectious disease accommodation, especially for small-pox. The slums are to be purified and abolished by closing unwholesome houses and by clearing insanitary areas. Public abattoirs are called for, together with the improvement or abolition of underground bakehouses. These points represent great obstacles that stand in the pathway of every large municipal authority, and some of them are also to be met with in the smaller towns and the country districts. Bristol has been well rewarded by its reduced death-rate for the steady, sagacious, yet withal moderate policy administered by its past and present Medical Officers of Health.

Excessive Ventilation.

The supply of fresh air in hospital wards has been ventilated of late in the Press with an insistence which suggests that there may be a real grievance calling for remedy. We may dismiss the allegations that draughts cause patients to develop pneumonia, but the actual discomfort which results from too direct a current of fresh, and often cold air, may well have a prejudicial effect on the sick. Moreover, the very existence of such currents of air testifies to an absence of scientific methods of dealing with the question of ventilation. It is possible to renew the air of wards as often as is required without the introduction of large quantities of cold air from the outside, and to turn windows into permanent inlets is an unscientific proceeding, a relic, in fact, of pre-sanitary days, utterly unworthy of the actual state of the science. This point should receive the attention of the authorities, for the comfort of patients is almost of as much importance as their treatment.

The Grievances of the Navy Medical Service.

That the condition of the Navy Medical Department is not satisfactory is conclusively proved by the dearth of candidates for that branch of the service. It has been estimated on good authority that the Navy at the present moment is short of at least fifty-seven officers on its peace footing alone. The reasons for that serious deficiency are obviously to be found in the unpopularity of the Service. The question has been dealt with in an incisive way by the *Naval and Military Record.* According to that journal all our naval officers are underpaid, and the key to the problem lies in granting naval surgeons pay and privileges equal to those enjoyed by their military *confrères.* In the Army there are sources of additional pay, such as Indian and staff and many other appointments, which are wanting in the Navy. The great difficulty with the Admiralty, in approaching an increase of pay for the Navy surgeons, appears to lie in the fact that a concession to the Medical Department would add to the existing discontent among combatant Navy officers at the relative inadequacy of their pay. Two wrongs do not make a right, however, and we agree emphatically with the editor of the above-quoted journal when he urges the necessity of facing the whole question. The gilt has been rubbed off the gingerbread so effectually that it is impossible for the Admiralty to fill up the vacancies in the Medical Department. What would happen, we wonder, in the event of a great naval war?

Lethal Halls.

The evil due to attending meetings in crowded and badly ventilated buildings is hardly estimated at its proper value, even by members of the medical profession. Everyone who has been for any length of time in an imperfectly ventilated church or theatre must be familiar with the symptoms of foul air poisoning. The headache, the feeling of sickness, the faintness, are well-recognised consequences of the mixed poison of carbonic acid gas and of organic effluvia thrown off from the lungs of those present. As a rule relief is obtained at once by the simple expedient of going out into the fresh air. Now and then, however, the results are more serious. At a recent meeting of the Rugby Guardians one of the members, Dr. T. S. Townsend, attributed the death of their late chairman to trouble that was in the first place due to the bad ventilation of the room in which they met. The illness of another Guardian he ascribed to the same cause. In his opinion they were all being slowly poisoned. After this strong indictment the Rugby Guardians will probably look about for more wholesome quarters, unless they are prepared to be decimated periodically in their zeal for public economy. The lesson to be learned from the incident is of wide application, and local bodies throughout the Kingdom might well lay the moral to heart. It would be better for everyone concerned were medical men more generally inclined to enforce the salutary maxims of hygiene in the practical manner adopted by Dr. Townsend.

An Unrepentant "Vanity Fair."

Our sprightly contemporary, *Vanity Fair*, which adds its weekly quota to the gaiety of the British nation, seems to take a malicious pleasure in holding up from time to time members of the medical profession to the public gaze in its cartoon pages. Why its editor should persist in forcing this unwelcome attention upon reluctant "medicoes"—as he is fond of calling them—is best known to himself, although possibly this stirring up of the waters represents good journalism—that is, from the point of view of circulation. In the issue of November 20th *Vanity Fair* publishes a letter from a correspondent anent Sir William Broadbent's condemnation in the *Lancet* of the lay journal's cartoon as "undesirable publicity." The writer urges that notice of that kind is simply a penalty of greatness. "There is a fierce light," he continues, "which beats upon the eminent politician, advocate, ecclesiastic, sailor, merchant, philanthropist, or criminal, even as it beats with fiercer light and more blazing indiscretion upon the occupant of a throne." This explanation lacks clearness. The only categories under which the medical man can be placed, *quâ* medical man, appear to be those of philanthropist or criminal. Philanthropy we believe to be a universal trait of the medical profession, but it is hardly of the kind that can derive additional lustre from the pencil of the cartoonist. The condemnation of the medical profession of this kind of publicity is complete and emphatic, and any editor who wilfully ignores that attitude can hardly be said to follow the unwritten laws of high-class journalism.

Primary Ether Narcosis.

Most anæsthetists are agreed that there is no anæsthetic so safe in ordinary work as ether, and consequently any extension of its field of applicability is of considerable interest. Ehrich and Ludeck have recently pointed out that after a few deep inhalations of ether there is a temporary narcosis, during which there is analgesia, though the sense of touch is not interfered with, and Ehrich has been in the habit of making use of this period for the performance of brief operations, such as the opening of boils or extraction of teeth. No special apparatus is necessary for such administration of ether, and in this way it has certain advantages over gas, so that the method at any rate deserves a trial.

Inadequate Hospital Reports.

The want of some sort of uniformity in the financial and administrative report of the medical charities has long been apparent. This abuse has been recognised by the Hospital Funds, and has to some limited extent been legislated against by those important distributing bodies who make a routine detailed return of certain specified facts, a condition preliminary to granting an award. Their action is commendable, and would be more so were it not accompanied by a tendency to sit in judgment and to travel far afield outside the function of distribution by imposing further and sometimes clearly ill-considered conditions upon the hospitals. A case in point is the withholding of a grant except on the completion of sale of a certain institution, a step which was explicitly condemned by at least two leading medical journals, and acknowledged by the committee concerned as not likely to prove of financial benefit to the hospital. It would be more in consonance with the objects for which the funds were created if they made every award conditional upon the publishing of a full statistical report. For instance, in order to obtain any clear idea of the economy and efficiency of a medical charity, it is absolutely necessary to know such details as the cost per head, the cost per patient, and the cost per bed occupied. Were the Funds to insist upon some such scheme of report they would be more likely to do justice to the hospitals, great and small, that are conducted upon principles of economy and sound finance. At present their system seems framed to encourage reckless and unbounded extravagance on the part of executive committees. The greater the debt the greater the claim upon the charitable public is apparently their accepted maxim.

Rectal Feeding.

Notwithstanding the manifold and conspicuous advantages of rectal feeding in certain diseased conditions, such as obstruction in some part of the alimentary canal, persistent vomiting, inanition, and so forth, it may be doubted whether the method is resorted to by medical men as frequently as it deserves. The chief cause of this unmerited degree of neglect is probably to be found in the disinclination of patients, so to speak, to reverse the current of alimentation by artificial means. Of the food that may be appropriately administered *per rectum* eggs appear to be most suitable, chiefly on account of their concentration of nutriment and their non-irritating nature. A fair allowance of salt, about fifteen or twenty grains to each egg, is a powerful aid to absorption, which is further promoted if the bowel be previously washed out with a simple warm water enema. Beef-tea and milk are not so suitable for injection, chiefly because of their large bulk in relation to nutritive value. Both should be well salted, a remark, indeed, which applies to all forms of rectal alimentation. Peptonised food is often useful, and is absorbed much more quickly than eggs, although the sustaining properties of the latter, in many cases, more than counterbalance the advantages due to a slower rate of absorption. Fat should be carefully avoided. Sugar is readily absorbed by the mucous membrane and may be given in quantities of an ounce or more daily dissolved in half a pint of water. Most practitioners will find themselves amply repayed, sooner or later, by a careful study of the facts of rectal feeding.

Reversed Peristalsis.

Most medical men have from time to time met with cases of obstinate constipation accompanied by vomiting, more or less fæcal in nature, where the natural downward course of the peristaltic movements seems to have fallen altogether into abeyance. The condition is always a serious one, for the patient gradually and speedily absorbs more and more fæcal poison, and unless appropriate treatment be instituted a fatal termination is not unlikely. A series of eighty-nine such cases has been investigated by Mr. Mohroof (*Indian Medical Gazette*, October, 1902), and he arrives at the conclusion that in most of them the peristaltic movement is not merely not abolished, but actually takes place in a reverse direction. In several cases he has seen enemata vomited, apparently unchanged, some minutes after the injection. As regards treatment, he holds that the administration of purgatives of any sort is not only injudicious but positively dangerous, and he recommends absolute abstention from food coupled with the administration of opium. In the course of two or three days the vomiting generally ceases, and the bowels may begin to act, the return to the normal being aided by massage of the abdomen.

Appendicitis in Mummies.

No one doubted that the disease now so well known under the barbaric name of appendicitis was of ancient lineage, although it is only within the last quarter of a century that its pathology has been elucidated. Still, it is rather startling to learn that indisputable evidences of appendicitis have been discovered in a certain number of Egyptian mummies. Dr. Lannelongue, of Paris, described the results of his investigations in this direction before the French Academy of Medicine last week. He is unfortunately not in a position to formulate any conclusions as to the frequency of the disease among the ancient Egyptians, although incidentally he asks us to infer that it has become much commoner of late owing to the more general consumption of meat, an hypothesis which will not command universal acceptance. Of course, food largely composed of albuminous substances is more amenable to decomposition, and the poisons elaborated by the micro-organisms which effect this change are more lethal than those which attack vegetable *debris*. It is therefore conceivable that such a food would offer a favourable pabulum for marauding microbes. It is, however, infinitely probable that the remarkable frequency of the disease at the present day is apparent rather than real, and is due merely to more exact diagnosis. The statistics of appendicitis, indeed, are open to the same fallacious interpretations as those of cancer, the prevalence of which is also in great measure a mere question of nomenclature.

Fanatics and the Public Health.

Dr. J. F. Dill has drawn the attention of the medical profession, in the course of a presidential address to the Brighton and Sussex Medico-Chirurgical Society, to the lamentable consequences which every day result from the unchecked dissemination of syphilitic infection. Surely, never were good motives prostituted to such a purpose as when weak-minded, though perhaps well-meaning, fanatics succeeded in turning the nation from the path, which would, by this time, have brought thousands of people to a new standard of health and strength instead of leaving them a prey to a loathsome disease and a source of danger to the most innocent of their neighbours. The opponents of the "C.D." Acts come of a stock whose *forte* consists in telling the nation, or the rulers of the nation, to "count the cost" of their actions in particular cases. Can they themselves ever estimate the cost of their ill-advised outcry, or tell the amount of misery, disease, and death which has been entailed on innocent people by that outcry? Dr. Dill's words are well worthy of repetition:—"We have with ease stamped out rabies, and our forefathers banished leprosy; we isolate the zymotic diseases, and quarantine small-pox, but if a man has syphilis he is permitted to transmit it to whom he will—to the child whom he kisses, to the first friend who smokes his pipe, or to the healthy and innocent girl whom he marries." The result, as the speaker pointed out, is that thousands of helpless infants and children suffer or perish from the most loathsome of all diseases, and thousands of men and women spend their life suffering through no fault of their own. This terrible legacy, which we are handing down to posterity, is not the result of ignorance of the cause and mode of infection. It is due to the fact that a certain section of the British race demanded what they considered to be an easy conscience even at the price of the misery of thousands.

Bequests of Brains.

Professor Wilder, of the Cornil University, U.S.A., is making a collection of brains for the purpose of scientific investigation. It is not particularly difficult to obtain the brains of criminals, paupers, and of the lowly in general, but for purposes of comparison a number of more highly-developed brains is of course indispensable, and it is here that the difficulty has arisen. Professor Wilder accordingly makes an appeal to eminent men of all denominations to place their brains at his disposal, and it is reported that a certain number have acquiesced in his demand, and have made testamentary arrangements accordingly. The Professor ultimately hopes to be enabled to throw light upon the vexed question whether the conformation of the brain is materially influenced hy studious habits and training; in other words, whether intellectual acquirements can in any degree be transmitted from parent to offspring. We know that big brains, like big bones or big muscles, are inherited as family traits, but it is also very apparent that the possession of a big brain is not necessarily associated with the desire or the ability to turn it to useful account. The qualities which go to make a really great man are many and varied, and the mere possession of a potentially active brain is perhaps not the most important factor in this direction. Physiological investigation throws no light upon the wonderful system of ramifications in virtue of which a person possesses to the full the intangible faculty of the associationship of ideas. This depends upon recondite anatomical structure, which so far has baffled the closest observation.

Hyoscin and Morphinism.

Attention has been directed recently, particularly in America, to the study of the treatment of morphinism, and it has usually been found necessary when morphia is withheld, to substitute temporarily some other sedative drug, which, in its turn, is withdrawn before its "habit" has been established. The most successful, and probably the most popular, of these secondary drugs is hyoscin, and it has become the fashion in such cases to prescribe it in large, even in massive, doses. As is natural after a trial of some years, a better knowledge of the physiological and toxic properties of the drug now prevails, and it is found that much caution is necessary in its use, and that anything in the way of a routine treatment by hyoscin is fraught with considerable risk. In a well considered and temperate article in a recent number of the *Medical News* (October 18th) Dr. Pettey, of Memphis, makes a vigorous protest against certain teachings regarding the use of hyoscin which have received the sanction of physicians of great authority. By an appeal to the records of his own practice he shows that there is no drug whose effects vary more widely with different individuals, and that even small doses, *e.g.*, one-hundredth of a grain, repeated twice with intervals of an hour, may produce disastrous results. The use of hyoscin is perhaps not so well known in this country as it ought to be, but if it is to be adopted, the possibility of individual idiosyncrasy must always be borne in mind.

Electricity in Medicine.

It seems not unlikely that within the next generation or two electricity will have become the universal servant of mankind. Recent wireless messages exchanged between England and America mark a new era, the extent of which it is difficult to imagine. Curiously enough, these achievements have been won by scientists who have not as yet been able to determine the exact nature of the mysterious and apparently all-pervading natural force with which they are dealing. An attitude of that kind is common enough in medicine, where the steady accumulation of facts often leads to sound deductions as to curative treatment which are perfectly effectual, although based upon empirical grounds. From recent observations it seems justifiable to hope that in no distant future we may find electricity a valuable agent in dealing with cancerous growths, a malady the origin of which is still unknown, in the shape of focus-tube radiations and currents of high frequency of interruption. One of the latest developments of applied medical electricity is the suggested production of local anæsthesia. A series of experiments have been reported to the French Academy of Science by M. Ledac, of Nantes. He claims to have produced complete anæsthesia in lower animals by the use of electric currents of from ten to thirty volts, interrupted from 150 to 200 times per second. The upshot of this investigation will be awaited with interest, for the advent of a safe anæsthetic such as this promises to be, whether local or general. would be a matter of considerable importance in the medical world.

The Harveian Society.

A discussion, which promises to be interesting, is to be opened at the meeting of the Harveian Society on Thursday, December 4th, by Mr. C. B. Lockwood, on "The Surgery of Acute Appendicitis." The discussion is open to any member of the medical profession who may desire to attend.

The Ætiology of Vesical Calculi.

The perennial subject of vesical calculus has recently been made the subject of a very interesting communication to current surgical literature by Mr. F. C. Madden, the recently-appointed Professor of Surgery in the Egyptian Government Medical School at Cairo. As might be expected, Professor Madden discusses the matter more especially from the standpoint of the Egyptian inquirer. He tells us that the development of a certain proportion of Egyptian calculi depends upon the presence of the pathological products of *Bilharzia hæmatobia* throughout the urinary system. It has been stated that the nucleus of many of those stones has been a Bilharzia ovum; but Professor Madden thinks that it is more reasonable to suppose that the nucleus really has been a piece of a papillomatous Bilharzia tumour (which would naturally contain ova) that had become detached and subsequently incrusted with phosphates. Certain calculi originating in this way are quite white in colour, and consist wholly of phosphatic salts. This is not surprising after one has seen the post-mortem appearances of an aggravated case of Bilharzia, which had affected the pelvis of each kidney, the ureters, bladder, and urethra. But *all* Egyptian calculi are not of Bilharzic origin, and a further explanation is easily ascertainable. The universal drink of the whole native population of that country is Nile water, which during some months of the year is known to be strongly impregnated with lime salts, gathered from the limestones of the country through which the river passes in a considerable part of its course. The natives of Egypt and of the Soudan are almost exclusively vegetarian in their diet; meat being taken only in small quantity, and usually, even then, in the form of soup, which only serves as a vehicle for vegetables. Green vegetables are the special favourites. It is suggested that excessive acidity of the urine develops from the continuous excretion of an unusual quantity of vegetable salts; and, accordingly, without any stimulus in the form of a nucleus, some combination of uric, or oxalic, acid occurs. This, of course, becomes deposited; and will continue to be deposited so long as the same causative factors persist.

Errors in Dispensing.

Some apprehension has been caused among the public of late by the occurrence of several fatal accidents due to errors in dispensing by medical practitioners. Obviously the practitioner who is inadvertently the cause of such an accident is almost as much to be pitied as his victim, but after reading the evidence given at the inquests it is impossible to resist the conclusion that the observance of certain elementary precautions would in every instance have obviated the fatal contingency. It cannot be denied that the dispensing doctor is more exposed to errors of this description than the dispensing chemist, whose attention is concentrated for the time being on the prescription before him. This not only places him on his guard against possible error, but he is also enabled to detect and rectify any slip in the prescription. The practitioner, on the contrary, has to do his dispensing after his return from his rounds, that is to say, when he is tired and his attention less on the alert. All the more reason, it may be urged, that he should take extra precautions to avoid the possibility of error, and it must be admitted that there is a margin for improvement in this respect. The simple precaution of keeping poisons in a special cupboard under lock and key, and the dispensing of poisonous liniments, &c., in bottles of distinctive colour and shape, would go far to avert the risk. Perhaps these lamentable mishaps will serve as a lesson to those who have had the good fortune to escape.

The Virchow Memorial.

A MEETING of the Virchow Memorial Committee was held on Friday evening last, with Lord Lister in the chair. In the course of his remarks the chairman concurred in the general principle that monuments of departed eminencies ought to be erected by their countrymen. To this rule, however, he admitted certain exceptions—as, for instance, in the case of Pasteur, whose scientific work had benefited all mankind. So, also, with Virchow, whose work in pathology had benefited the study of medicine throughout the world. It was announced that over a hundred adhesions had already come in, and the chairman, in disadvising any limit to the amount of subscriptions, made the novel suggestion, one worthy of more general adoption, that the amounts contributed by individuals should not be published. Public opinion will, we feel sure, thoroughly endorse Lord Lister's estimate of the value and cosmopolitan importance of the late Professor Virchow's labours. It may truly be said that his teaching was not "accepted," for it imposed itself. It altered the whole status of pathology and illuminated departments of study previously pursued under the depressing influence of *quasi*-obscurity. In this sense every pathologist in the world was a pupil of Virchow's, and it was meet and proper that all should be permitted to testify respect and admiration for their departed master.

The Gospel of Fresh Air.

THE virtue of the open window is unquestionably making headway, and the gradual spread of the gospel of fresh air among the working-classes will, in the long run, be productive of the greatest benefit. Unfortunately in our large towns the aggregation of inhabitants in comparatively small areas gives rise to more or less noise, part of which is distinctly avoidable. The open window, as many find to their cost, admits noise even more freely than fresh air, and sound sleep is thereby often rendered impossible for people of sensitive nerves. This question of unnecessary noise has begun to attract the attention of the public, but much remains to be done in the way of municipal legislation before we can hope to rejoice in peaceable nights. Large numbers of cats and dogs will have to be suppressed or rendered aphonic, the abuse of musical instruments will have to be checked, and drunken roysterers will have to be made to understand that the street is not the place for cacophonous manifestations. The open window will never become as popular as it should be until more attention is paid to this wanton disturbance of the night's repose, and it may be anticipated that the public will become more and more intolerant of these "aids to insomnia."

Ichthyol in Rheumatism.

LOOKING over a well-known book on therapeutics we alighted on the article "Rheumatism," and finding a long list of remedies for the disease in its many forms, we were tempted to tot up the number of remedies for this very common disease. We found they numbered 147, yet the list did not include ichthyol. And, as Dr. Post writes very favourably of the drug, we see no reason why it should not be added to the already long list. He uses it as a local application to swollen, tender, and painful joints. Having given a brisk cathartic with full doses of the salicylate of sodium, he paints the joints with pure ichthyol, and then covers them with oiled silk. This coating is renewed every eight hours until the joint can be freely moved without causing pain. In one case an elderly woman suffering from chronic rheumatism of the hip-joint so severe as to necessitate the patient to keep her couch, a fifty per cent. of ichthyol ointment well rubbed over the trochanters night and morning together with two drop doses of ichthyol in glycerine and peppermint water after meals, so far benefited the patient that she was able to walk about the house, and in fine weather to go out of doors. The drug is an ill-smelling one, and when given internally is usually, if not always, followed by unpleasant eructations; withal a patient suffering from chronic rheumatic arthritis of the hip-joint will be thankful for any drug that brings relief, and ichthyol is worth trying.

Dangers of Picric Acid as a Surgical Dressing.

IT is one of the disadvantages of fancy titles for chemical products that they give no clue to their chemical composition. The name picric acid is of this description. Under the classical designation, cartazotia, the prescriber learned somewhat of its composition, and did not prescribe it indiscriminately for all surgical wounds; the name told of toxic, if not lethal, properties. These toxic properties of the acid were well marked in a case recorded by M. Manseau, in which he applied one per cent. solution of picric acid to an extensive scald in a child. Marked symptoms of poisoning arose, while the urine gave the characteristic reaction for the acid. On discontinuing the acid, all the toxic symptoms disappeared.

The Irish Medical Schools' and Graduates' Association.

The Autumn Dinner of the Irish Medical Schools' and Graduates' Association will be held at the Hotel Cecil this (Wednesday) evening, when Earl and Countess Roberts will honour the Association by their presence. Tickets may be obtained by members from the Hon. Secretary, J. H. Swanton, 40, Harley Street, W. The usual meeting will take place in the afternoon preceding the dinner.

King's College.

It is announced that a Bill will be brought in next Session to abolish religious tests as a qualification as a member of the College, and for the holding of any office under the same, except the Professorship of Theology.

PERSONAL.

Dr. C. O'Brien Harding has been elected Mayor of Eastbourne.

Professor Koch is about to visit South Africa for the purpose of investigating the prevalence of cattle disease.

Mr. E. E. Glynn, M.B.Cantab., L.R.C.P., has been elected Assistant Physician to the Royal Infirmary, Liverpool.

Dr. J. A. Lawson has been accorded a grant of £500 from the Government of Hong Kong on his retirement, owing to ill-health, from service.

Mr. W. Watson Cheyne, F.R.S., will preside at the Annual Dinner of the Harveian Society, which is to take place at the Café Monico on December 11th.

Dr. Louis C. Parkes, Medical Officer of Health for Chelsea, will open a discussion on "Drain Testing" at a meeting of the Sanitary Institute (Parkes Museum) on December 10th.

Dr. Sydney A. Monckton Copeman, of the Local Government Board, has been awarded the Buchanan Medal for his experimental investigations into the bacteriology and comparative pathology of vaccination.

Mr. C. R. C. Lyster, formerly Medical Superintendent of the Bolingbroke Hospital, has been appointed to the newly-created office of Medical Officer to the Finsen Light and X-ray Department of the Middlesex Hospital.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

SCOTLAND.

[FROM OUR OWN CORRESPONDENTS.]

Resignation of the Principal of Edinburgh University.—At a meeting of the University Court on November 17th, Sir William Muir intimated his resignation of the Principalship, on the ground that, after his late illness, he no longer felt equal to the duties which he had for so long had the privilege and honour of discharging, not only with pleasure and profit to himself, but also in the enjoyment of kindly fellowship with all the Professors and friends of the Court and Senatus. With these it had been his privilege to have been long associated, and above all, with the old University itself, with which, including a season of student life, it had been his happy lot to be associated for nearly a score of years, and from which he could not now part without sincere sorrow and affectionate regret. The Court accepted the resignation, to take effect as from the appointment of a successor, and instructed the secretary to communicate with the curators, in whose hands (and not, as in the case of the other Scottish Universities, with the Crown) the appointment lies. The curators consist of Dr. Heron Watson, Lord Stormonth-Darling, Colonel Forbes Mackay, Sir Andrew Macdonald, the Lord Provost and Treasurer Cranston. Sir William Muir was born in 1819, was educated at Kilmarnock, and Edinburgh and Glasgow Universities, and, after attending the East India Company's College at Haileybury, proceeded to India in 1837. There he was promoted to be Collector at Futtehpore in 1843, and ten years later became Secretary to the Governor of the N.W. Provinces. He was one of those shut up in Agra fort during the Mutiny, and subsequently joined Lord Canning as Secretary at Allahabad, and became member of the Legislative Council and Foreign Secretary to the Government of India. He then became in succession, member of the Governor-General's Council, Lieutenant-Governor of the N.W. Provinces, and Chancellor of the Indian Exchequer. On retiring from the service he retained an active connection with Indian affairs until 1885, by becoming a member of the Indian Council in London, a position which he then resigned on being appointed Principal of the University of Edinburgh. In addition to his great administrative capacity Sir William Muir possesses a considerable reputation among Oriental scholars as the author of a "Life of Mahomet," a "History of the Caliphate," and a work on the Koran.

Notification of Phthisis.—As an outcome of the circular requesting the co-operation of the medical profession in the voluntary notification of phthisis issued some weeks ago by the Medical Officer of Health for Edinburgh, a special meeting of the Medico-Chirurgical Society was held to consider the matter. A paper on the subject was read by Dr. Henry Littlejohn, and discussed by the convener of the Public Health Committee, Dr. Leslie Mackenzie, Medical Adviser to the Local Government Board, Dr. Lawson, Dr. Philip, and Dr. Gulland. A resolution in favour of compulsory notification was adopted.

Gift to the Royal Infirmary, Edinburgh.—Professor Chiene has presented an interesting relic to this institution. It is an old student's hospital ticket, dated 1768. The ticket, which has the name of Professor Goodser's grandfather on it, is printed on the back of an old playing card, the ten of clubs.

MANCHESTER.

[FROM OUR OWN CORRESPONDENTS.]

The Central Midwives Board.—The nomination of Professor W. J. Sinclair to the Central Midwives Board has caused great satisfaction in this district. Being nominated by the Lord President of the Council, Dr. Sinclair's position on the Board will be one of great independence and freedom of action—more so than those of his colleagues who represent the Royal College of Physicians and Surgeons, the Society of Apothecaries, and the Incorporated Midwives Institute. Medical readers will remember that no man has suffered in the past more misrepresentation and abuse at the hands of the anti-midwives party than has Dr. Sinclair. There is therefore an element of poetic justice in the Lord President's nomination of his medical representative.

Lancashire, with its colossal working-class population, is perhaps the part of all England where there will be in the future the greatest need and scope for the work of well-trained midwives. It is well, therefore, that the Central Midwives Board should have at its disposal full and accurate information as to the conditions of medical work in this district. This is made doubly secure by the presence on the Board, together with our present Professor of Obstetrics, of Dr. C. J. Cullingworth, who, of course, is also a Manchester man.

It is perhaps permissible to remark that, while better than nothing at all, the Midwives Bill is by no means a strong or a very good instrument to work with. We should go so far as to say that its success or its practical failure will depend entirely upon the skill, judgment, and firmness with which the Board does its work. The framing of regulations for the working of the Bill will demand strenuous work from brains of the highest order. The brains are forthcoming, but the owners are busy people, and many sacrifices will be necessary on their part, more especially during the earlier portion of their work. It is to be hoped that their efforts will not be hampered by premature criticism and unmerited abuse.

BELFAST.

[FROM OUR OWN CORRESPONDENT.]

Students' Reception for Sir Wm. Whitla.—On Saturday evening, the 22nd, a very successful smoking concert was given in the Great Hall of the Students' Union, Queen's College, in honour of Sir Wm. Whitla. The students of the college, with Professor Symington as their chairman, acted as hosts, and the guests included the professors of the college and the medical men connected with the various teaching hospitals of the city, who, with very few exceptions, were present to do honour to their colleague.

Professor Symington proposed the health of the guest of the evening in a brief and humorous speech, in which he remarked that though formal resolutions and addresses of congratulation might do for municipal bodies or college councils, students believed in something more personal, and liked to express their good feelings face to face. The toast was honoured with cheers that shook the building, and Sir William Whitla responded in a graceful and warm-hearted speech. In the course of it he said that frontal convolutions, trained to study the virtues of scammony and aloes, were at a loss when called on for such duties as were imposed on them that evening, and that there was risk that the very warm reception he had been accorded, instead of stimulating them to a great effort, might produce the effect which an over-stimulus sometimes did, namely, paralysis of their functions. A capital programme of music was given in an atmosphere pleasantly redolent of the fumes of tobacco and coffee.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE TREATMENT OF CHRONIC INVERSION OF THE UTERUS.

To the Editor of The Medical Press and Circular.

Sir,—I listened to the interesting paper and subsequent discussion on Mr. John Taylor's case of above at meeting of Obstetrical Society, October 1st. Dr. Heywood Smith spoke of manual compression of the organ, and this reminded me of a plan I am tempted to describe, adopted by myself in a case of the kind I met with several years ago, in the hope that others, having more opportunity of treating such cases, may be induced to give my plan a trial before adopting more heroic measures.

I was told the patient had suffered for eight years and had been seen by several medical men, and had (she informed me herself) been at Aberystwyth Hospital, where efforts had been made to cure her without success. Indeed, she strongly objected to any interference or examination, and it speaks well for the persuasive powers of an Irishman to be able to state she at length consented to my examining her, but only on the condition that she should be anæsthetised. Having had her placed under chloroform, I found the case one of chronic inversion, and made efforts by manipulation and pressure combined, with scarification and hot stuping of the uterus (water hot as my hand could bear), to reduce the inversion, but failed.

However, having observed some retraction and shrinking, and having no repositor at hand, it struck me to treat the case like one of "paraphimosis," and, having procured some narrow flat rubber tape, I encircled the uterus from below up, and fastened off less tightly at constriction. I then allowed patient to recover from anæsthetic and inserted a grain morphia suppository, and, having seen that all was right, left her till next day, when I found the protrusion much smaller (the patient complaining of pain again, as the effects of morphia had passed off). I unwound the rubber band and reapplied it, inserted another suppository, and that evening I had the satisfaction of being able to replace the uterus. I may add manual pressure was made at either corner alternately, and as one side yielded I made pressure on opposite side, and so, by zig-zag movements, the whole organ slipped up suddenly with a jerk.

The patient recovered completely, and instead of being obliged each day to sit on a commode with blankets round her limbs from morning till night (as she assured me she had done for several years), she conceived and bore a son, which fact I was quite unaware of, having left the district (North Wales), but the vicar of the town kindly wrote informing me, and congratulating me, as he had taken a great interest in her case for years. I imagine the treatment I have endeavoured to describe might deserve a trial in these uncommon cases, as, so far as I can discover, it is original.

I am, Sir, yours truly,
Alexander Duke.

THE PORTRAITS OF MEDICAL MEN.

To the Editor of The Medical Press and Circular.

Sir,—Change in the methods of portraiture and decay in the products of the engraver and lithographer, and forgetfulness, and worse, on the part of many moderns, are robbing us of the ancient representations of medical worthies of a bygone time. A generation that neglects to honour its ancestors is likely to be speedily forgotten by its progeny. I think there must be many prints, photographs, or engravings of those who have laboured long and well in the making of medicine stowed away in old portfolios or lying in forgotten corners. Before such have altogether passed beyond our reach it would be well if serious effort could be made to save them from destruction. I venture to think that our various hospitals and medical schools might wisely assist in securing the protection of all portraits and interesting relics linking us to the distinguished practitioners of the past,

Yours faithfully, T. N. K.

"THE ALCOHOLISATION OF WOMEN."

To the Editor of The Medical Press and Circular.

Sir,—Is it at all proved that abuse of alcoholic drinks is on the increase among women of any class? I, for one, seriously doubt the statement; and my doubt is based, not only upon sufficiently close observation for many years of female patients of the better classes, but upon social intercourse, with eyes open, among these classes. The signs of chronic alcoholism are nowhere more easily to be detected by the experienced eye and nose than in the mouth and breath. The mucous membrane of the mouth of those who take alcohol to excess always assumes a characteristic appearance, whilst the odour of the breath is in most cases unmistakable. As a specialist whose patients are mostly women, I fail to find anything like the number of suspicious cases nowadays that were recognisable twenty-five years ago. Socially, my experience has been in late years that more and more women abstain from wine at dinner, and very rarely indeed do I notice (although, I repeat, my eyes are open) a woman to whom wine seems an irresistible temptation. Certainly there is less drinking among men above a certain class; and, if fathers and brothers drink less, why should we suspect mothers and daughters to drink more? A higher standard of health than ever prevails among the majority of women to-day, thanks to the athleticism with which they are imbued as girls, and which they do not, in most cases, altogether neglect as women. I venture to affirm that if you, Sir, would issue to your subscribers and readers a few questions as to their experiences and opinions on the subject, you would find an overwhelming majority to agree with the view which I have here expressed.

I am, Sir, yours truly,

Nov. 21, 1902. H. S.

Literature.

ROSE AND CARLESS'S MANUAL OF SURGERY. (a)

It literally speaks volumes for the progress of surgery at the present day that although this, the fifth edition, comes to us within twelve months of the fourth, considerable modifications have been found necessary to bring the work up to date and to fit it more satisfactorily to modern requirements. Part of the change savours of a mere shuffling of the cards, as, for instance, the relegation of the phenomena of inflammation and its treatment to a back seat, in order to give precedence to bacteriology, the youngest and most self-assertive of the sciences germane to medicine, and the principles of antiseptic surgery.

This departure from time-honoured precedent is, however, not without its special significance. We all feel proud the day we are admitted by the front door instead of passing down the area steps, for it is an indication that we have risen in social status. Bacteriology, as a young, living science, long regarded askance, might, had it a biological existence, experience similar satisfaction. The change in short, is an "act of notoriety" which proclaims the greater importance of understanding the etiology of inflammation over its mere manifestations. Seeing that antisepsis has for many years been the foundation stone of surgery, it is only meet that its principles and application should be accorded a place of honour in all treatises dealing with that art.

On looking through this edition we find that the other changes do not embody any particular innovation of epoch-marking interest, though they "lead to a more harmonious pathological and clinical picture than was previously presented"—but that is saying a good deal in view of the fact that the literary and technical excellence of its predecessors was such as to almost sweep the field of rivals, thereby securing a popularity quite phenomenal in extent and degree.

Radiography *vel* skiagraphy has revolutionised certain branches of surgery by rendering internal injuries, such as fractures and dislocations, as easy of diagnosis as a laceration of the integument. It also enables us to see for ourselves whether, after reduction, the position of the fractured or displaced surfaces are in perfect apposition. The value of the method is demonstrated by a series of admirable skiagrams, lent by Messrs. Allen and Hanbury, which show to what perfection this neo-photographic development has attained.

In a fifth edition one hardly expects to discover many opportunities to exercise the critical function. There are, here and there, minor points to which one might take exception. For instance, in the treatment of furuncles it seems to be assumed that the local inflammation must necessarily go on to suppuration, and poulticing is practically the only measure suggested. Practitioners know, however, that they can be aborted early by timely incision and the application of pure carbolic acid. Then, too, the authors have re-edited an ancient and obsolete objection to Junker's inhaler for chloroform, viz., that it is possible to pump the liquid chloroform through the efferent tube by accident. As a matter of fact this was rendered impossible years ago by a simple contrivance with which every apparatus has since been provided. We could have wished, too, that the authors had emphasised the importance of employing this apparatus more generally for the induction of anæsthesia, since it is unquestionably more rational and safer than the mask or towel, *pace* the Scotch school of anæsthetists.

It only remains for us to congratulate the authors on the general excellence of a work which seems likely to be *the* text-book for many years to come. The volume is admirably printed and solidly bound, and it can be opened wide without eliciting the ominous crack which so often heralds partial destruction in books of this portly size—for it runs into upwards of 1,200 pages.

COLBECK ON PRESCRIBING. (a)

If this little work answers its purpose of assisting the student and practitioner in the practical application of drugs in the treatment of disease it will be doing something towards remedying a regretable lapsus in medical education. The growing habit of using ready-made combinations of drugs is probably not the cause, but the result, of a system of medical training which relegates pharmacy, materia medica, and applied therapeutics to the background.

After the chapters on prescription-writing, incompatibility and methods of administration, we come to the application of the methods of prescribing for diseases of the various systems—digestive, cardio-vascular, respiratory, &c. Under each head model formulæ are given for the relief of the prominent symptoms and, so far as they go, they are unexceptionable, but they leave the impression that our therapeutical resources are, after all, very limited, the changes being rung on a comparatively small number of drugs. We look in vain for any ingenious combinations outside the beaten track, but, on the other hand, the authors do not pretend to do more than guide the uncertain hand of the tyro, so that we are perhaps not entitled to expect more than they have given us.

The practical value of the work would be greatly enhanced by a more copious index. A means might easily be devised to enable a reader who wishes to prescribe, let us say arsenic and iron, or iron and a vegetable bitter, to refer forthwith to a model prescription containing this or that association of drugs. As a matter of fact, there is no index reference to drugs at all. This is a defect which might easily be remedied in a future edition. An attempt might also be made to break away from bismuth and soda for indigestion, ipecacuanha and paregoric for cough, and the many other venerable formulæ, in favour of equally "model" if less hackneyed associations.

STELWAGON ON SKIN DISEASES. (b)

It cannot be said that there is any lack of treatises on diseases of the skin by English authors, yet this one by an American dermatologist will doubtless be welcomed by many, not only on account of the comprehensiveness of the information conveyed in the text, but also, especially, for the sake of the numerous coloured plates, which are of unusual excellence and finish. There are twenty-six full-page lithographic and half-tone plates, and no less than 220 illustrations in the text. This wealth of illustration in a work treating of diseases of the skin is especially welcome, because the most careful and detailed descriptions inevitably fail, in many instances, to convey a clear clinical idea of the lesions which can only be understood when seen.

Special attention has been given to the diagnosis of the various cutaneous affections, and the author may be allowed to have achieved all that word-painting can do with the object of facilitating the task. In the matter of treatment it is decidedly a satisfactory feature that the author is careful to point out not only what, in a general way, is to be prescribed, but, whenever possible, to give definite directions as to selection and method.

This is not the place to challenge the author's views on certain questions of classification and nomenclature, although there are sundry points which invite discussion.

(a) "A Manual of Surgery for Students and Practitioners." By William Rose, M.B., B.S.Lond., F.R.C.S., Professor of Clinical Surgery in King's College, London, and Senior Surgeon to King's College Hospital, &c., and Albert Carless, M.S.Lond., F.R.C.S., Surgeon to King's College Hospital and Teacher of Operative Surgery in King's College, London, &c. Fifth Edition. Price 21s. net. London: Baillière, Tindall and Cox. 1909.

(a) "The Science and Art of Prescribing." By E. H. Colbeck, B.A., M.D.Cantab., F.R.C.S.Lond., and Arnold Chaplin, B.A. M.D.Cantab., M.R.C.P.Lond. Price 5s. net. London: Henry Kimpton. 1902.

(b) Treatise on Diseases of the Skin." By Henry W. Stelwagon, M.D., Ph.D., Clinical Professor of Dermatology in the Jefferson Medical College and Woman's Medical College, Philadelphia, &c., &c. B. Saunders and Co. 1902.

The work is provided with a very copious index, which even goes so far as to give the French and, in some cases, the German equivalents for the diseases. This fact affords an indication of the care and thoroughness with which the work has been carried through.

LITERARY NOTES.—We understand that Mrs. Alec Tweedie is bringing out a new and cheaper edition of the very charming memoir of her father, "George Harley, F.R.S., or, the Life of a London Physician."

THOSE medical men who are seeking admission to the Bar, will be interested to read the article in the current number of the *Cornhill*, on "Prospects in the Professions." It has become somewhat of a fashion among a certain class of medical specialists to seek rank as a barrister-at-law. The article to which we have referred indicates that it is as hard to succeed in the profession as it is easy to enter it.

Medical News.

The Action Against the Apollinaris Company.

THE proceedings instituted against the Apollinaris Company for falsely describing the water as "natural mineral water" ended in the case being dismissed by the magistrate on the ground that there was no legal definition of what constituted a natural mineral water, especially in view of the fact that in the case before him there was no addition of a foreign substance in the fair sense of the term. From a common-sense point of view, manipulations which have for object merely to ensure the preservation and the dietetic excellence of the article would not appear to confer the description of "artificial."

Death from Pyæmia.

MR. M. WOOD, M.R.C.S., who was acting as *locum tenens* at the Huntingdon County Hospital in consequence of the incapacity of the resident medical officer from septic poisoning of the hand contracted in the course of a post-mortem examination, himself contracted septic infection, to which he succumbed after a few days' illness.

Another Hospital Fire.

AN outbreak of fire occurred on Friday evening last in the laundry of the Royal Free Hospital, Gray's Inn Road, and for a time great alarm prevailed, but it was ultimately extinguished before it had spread to the wards.

Dublin Death-rate.

THE deaths registered in the Dublin registration area for the week ending Saturday, November 15th, 1902, represent an annual rate of mortality of 27·8 in every 1,000 of the population. They included 26 deaths from tuberculous disease: 14 from diseases of the nervous system; 39 from diseases of the circulatory system; and 37 deaths from diseases of the respiratory system; 72 children died during the week, of whom 41 were under one year old. In Clarence Street North District the death-rate was 38·6; in Summer Hill District 39·2; in Lisburn Street District 46·8; and in Blackhall Place District 37·9 in every 1,000 of its population.

Death from Chloroform.

AN inquest was held last week on a miner who had died under chloroform, administered for the fourth or fifth time, at the General Hospital, Wolverhampton. Death could not very well be attributed to idiosyncrasy, since the deceased had previously taken it well, so a verdict of death from cardiac failure was returned.

West Norfolk and Lynn Hospital

A NEW operating theatre being required for the West Norfolk and Lynn Hospital, the King has headed the list of subscriptions with 100 guineas, the Queen contributing £100, and the Earl of Leicester (Lord Lieutenant of Norfolk) a similar amount.

Dublin University Biological Society.

ON Thursday, the 27th inst., the opening meeting of this Society will be held in the Front Hall. The president will read the inaugural address, his subject being "Tuberculosis: Its Relation to Public Health." The chair will be taken at 8.15 p.m., by Dr. R. Travers Smith, and the speakers will include Sir John Wm. Moore, M.D., and Sir Thomas Pile, Bart.

Mr. Allinson as an Anti-Vaccinator.

DETERMINED not to miss any opportunity of cultivating the notoriety which is a poor substitute for fame, Mr. Allinson, ex-L.R.C.P., applied for, and obtained, a certificate of exemption from vaccination for his child. He based his application on the "fact" (!) that when engaged as an assistant public vaccinator he "saw any amount of injury, and even a good many deaths." As all this injury and death was presumably of his own doing, Mr. Allinson must bear the responsibility and not seek to burden the operation with powers for mischief, which have certainly not been discovered in the hands of others. Mr. Allinson particularly resented having to pay one shilling for the certificate, but he paid it after some grumbling.

Guy's Hospital War Memorial.

THE Guy's Hospital South African Memorial Committee is anxious that none of the names of Guy's students who lost their lives in the war should be missing from the record on the memorial, which is to take the form of a drinking-fountain in the colonnade, from a design by Mr. Frederick Wheeler, F.R.I.B.A. Dr. Frederick Taylor, the senior physician, will be glad to hear from any of our readers who can assist in the completion of the record.

◆

Pass Lists.

Royal College of Surgeons, Ireland.

THE following candidates have passed the Primary part of the Fellowship examination:—Miss A. M. Barry, Miss E. J. Jellett, Miss J. C. Hargrave, Miss T. E. Harrison, Mr. G. A. D. Harvey, Miss I. G. Ovenden, and Mr. J. Parker.

The following candidates having passed the Final examination, have been admitted Fellows of the College:—Mr. F. J. C. Heaney, Mr. C. F. Marks, Mr. G. S. L'Estrange, Miss M. S. P. Strangman, and Miss M. Thom.

Trinity College, Dublin.—Michaelmas, 1902.

THE following gentlemen have passed the Final Examination in Surgery:—John H. Torney, Thompson F. Wilson, Maurice FitzGibbon, Charles A. Stone, Anthony H. Corley, James M'Cutcheon, William P. Ringland, Thomas W. Crowley, William Leggett, James E. Johnstone, Henry B. Kelly, Nicholas M. Cummins, Charles Rolleston.

B.Ch. Degree.—Henry A. Hanan.

Society of Apothecaries of London.

THE following candidates passed in:—

Surgery.—A. E. Bird (Sections I. and II.), G. M. Crockett (Sections I. and II.), B. M. Dunstan (Section II.), L. Ettinger, G. R. Hannon, R. J. O. Harley, L. J. A. Marry, J. P. Nettell (Section I.).

Medicine.—A. E. Bird (Section I.), T. S. Davies, H. B. Drake (Section I.), O. Gutermann, R. J. O. Harley, W. Martin (Section I. and II.), L. J. A. Marry, C. C. Rushton (Section I).

Forensic Medicine.—F. G. Bennett, A. E. Bird, H. B. Drake, L. Ettinger, I. Griffith, O. Gutermann, W. Martin, L. J. A. Marry, C. C. Rushton, L. S. Shoosmith.

Midwifery.—J. Bromley, J. D. Keir, L. H. Lewis, G. Lucas, L. J. A. Marry, E. H. Price, H. Smith.

The diploma of the Society was granted to the following candidates, entitling them to practice Medicine, Surgery, and Midwifery:—F. G. Bennett, I. Griffith, and L. J. A. Marry.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.

WE are requested by a subscriber to solicit support on behalf of the candidature of Robert Kirkpatrick MacRoberts, aged nine, son of the late William Kirkpatrick MacRoberts, M.B., M.Ch., &c., formerly practising at Burton-on-Trent, and late of New South Wales, where he was appointed Physician in charge of the Wentworth Hospital, and Medical Officer of Health for the Central District. Dr. Kirkpatrick was killed by a fall from his horse on his way to visit a patient, leaving his wife and three children unprovided for. The candidature is endorsed by the Archbishop of Dublin, Earl Roberts, the Right Hon. C. T. Ritchie, Prof. C. B. Ball, Dr. John William Moore, of the University of Dublin, &c. The case appears to be one deserving of sympathy and support, and we have pleasure in bringing it to the notice of our readers in view of the 1903 election.

MESSRS. FAIRCHILD BROS. and FOSTER, of New York, the manufacturers of the well-known series of digestive ferments and preparations, have produced for the use of practitioners two little booklets which cannot fail to be found useful. One contains recipes for the preparation of peptonised foods by the "Fairchild" process; the other a series of "diet slips," conveniently arranged for immediate reference, giving directions for the alimentation of patients suffering from the commoner complaints. The digestive products of this firm are too well known to medical men for it to be necessary to mention them in detail.

A DUTCH DEATH NOTICE.

ON the 28th inst., Amy Jane Mary Smit, eldest daughter of John and William Smit, aged 1 day 2¼ hours. The bereaved and heartbroken parents beg to tender their hearty thanks to Dr. Jones for his unremitting attention during the illness of the deceased, and for the moderate brevity of his bill. Also to Mrs. Williams for the loan of clean sheets, to Mr. Wilson for running for the doctor, and to Mr. Robinson for recommending mustard plaster.—*Krugersdorp Sentinel.*

UBIQUE.—The presence of a third person at an interview of the kind is absolutely necessary, in order that there may be confirmatory evidence of the statements made.

UNNECESSARY CANDOUR.

A CASE in which honesty is not the best policy, suggests a ribald contemporary, was that in which a medical man, in filling up a certificate of death, entered his name in the space allotted to the cause of death.

THE CLINICAL THERMOMETER.

CURRIE, of Edinburgh, employed a thermometer in the treatment of typhoid fever patients with the cold douche as early as 1797. He was ridiculed by his German contemporaries as an instance of medical decay in English medicine. The first clinical application of the thermometer was made by Santorius, of Padua. He invented a thermometer open at the end. After being held by the patient it was plunged into cold water. Boerhaave taught the importance of the thermometer. De Haen—1704 to 1776—must be given the honour of introducing the thermometer into current use at the bedside. It was not until 1850 to 1870 that it came into general use.

Meetings of the Societies, &c.

LONDON.

WEDNESDAY, NOVEMBER 26TH.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover Square, W.).—5 p.m. Dr. J. H. Stowers: Presidential Address.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8.30 p.m. Pathological Evening.

THURSDAY, NOVEMBER 27TH.

CHILDHOOD SOCIETY (Library of the Sanitary Institute, Margaret Street, W.).—8 p.m. Lantern Lecture: Mr. C. F. F. Campbell. The Practical Training of the Blind as carried on at the Royal Normal College for the Blind, Upper Norwood, S.E.

HARVEIAN SOCIETY OF LONDON (Café Monico).—6.30 for 7 p.m. Harveian Dinner.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—4 p.m. Dr. Seymour Taylor: Enteric Fever.

FRIDAY, NOVEMBER 28TH.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8.30 p.m. Papers: Mr. A. W. Mayo Robson: Ruptured Crucial Ligaments and their Repair by Operation.—Lieutenant-Colonel W. K. Hatch, I.M.S.: On Hepatic Abscess.—Mr. L. H. McGavin: A Case of Strangulated Inguinal Hernia in which Reduction *en masse* was caused by the Employment of Taxis.

TUESDAY, DECEMBER 2ND.

WESTMINSTER HOSPITAL (Broad Sanctuary, S.W.).—Dr. de Havilland Hall: Medical Cases. (Post-Graduate Clinical Demonstrations).

THURSDAY, DECEMBER 4TH.

RONTGEN SOCIETY (20, Hanover Square, W.).—8.30 p.m. Ordinary General Meeting. Dr. D. Walsh: An Observation Bearing upon the Therapeutic Action of the Focus Tube.—Mr. Stephen Mayou, F.R.C.S.: Paper.—X Rays in Ophthalmic Work, with lantern slides.—Mr. Isenthal: The Nodon Electric Valve for Converting Alternating into Continuous Current.

DUBLIN.

FRIDAY, NOVEMBER 28TH.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Obstetric Section—Exhibits by Card:—Dr. Smyly: (1) Three uteri removed for Myomata; (2) Uterus removed for Cancer; (3) Tubes removed for Tubercle. Dr. A. Smith: (1) Omental Tumour simulating an Ovarian Cyst; (2) Ruptured Tube (ectopic gestation); (3) Double Pyosalpinx, with large Ovarian Abscess Sac; (4) Broad Ligament Fibroid: (5) Typical Specimens of Ovarian Cystomata. Dr. Elena: Sarcoma of Ovary. Specimens:—Dr. E. H. Tweedy: (1) Tubal Pregnancy; (2) Ovarian Cyst and Pyosalpinx; (3) Salpingitis: two cases. Papers:—Dr. F. H. Tweedy: Tubal Disease; an analysis of four cases. Dr. Knott: A Case of Amenorrhœa. Drs. Neill and McWeeney: A Case of Eclampsia.

Appointments.

CORCORAN, THOMAS, L.R.C.S.I., L.A.H.Dub., reappointed Medical Officer of Health to the Loughborough Rural District Council.

DOWDING, A. W. WOODMAN, M.D., M.S.Durh., M.R.C.P.Edin.: M.R.C.S., L.S.A., Medical Officer for the Newlyn East District by the St. Columb (Cornwall) Board of Guardians.

GLYNN, E. E., M.B.Cantab., L.R.C.P., Assistant Physician at the Royal Infirmary, Liverpool.

HARSANT, WILLIAM HENRY, F.R.C.S.Eng., L.S.A., Honorary Consulting Surgeon to the Bristol Royal Infirmary.

IRVINE, R. C., M.B., Ch.B.Edin., House Physician to the David Lewis Northern Hospital, Liverpool.

JOHNSON, J. A., M.B., Ch.B.Vict., Assistant House Surgeon to the David Lewis Northern Hospital, Liverpool.

JOYNES, FRANCIS JAMES, M.R.C.S., L.S.A., Medical Officer of Health for the Dursley (Gloucestershire) Rural District Council.

MACKENZIE, F. S., M.B., Ch.B.Edin., House Surgeon to the David Lewis Northern Hospital, Liverpool.

MATHEWSON, JOHN, M.B., B.Ch., R.U.I., appointed District Medical Officer of the Bromley Union.

MOORE, STANLEY, L.R.Q.C.P.I., Certifying Surgeon under the Factory Act for the Maynooth District of the County of Kildare.

PITT, C. W., M.R.C.S., L.S.A., Medical Officer of Health for Malmesbury.

SCOTT, FRANCIS, M.R.C.S. and L.M.Eng., L.S.A., Public Vaccinator for the Tintern District by the Chepstow Board of Guardians.

STABB, A. F., M.B.Cantab., University Lecturer in Midwifery.

TICKELL, HENRY MAURICE, M.A., M.D., B.C.Cantab., M.R.C.S., Assistant Physician at Nordrach Sanatorium (Baden, Black Forest).

Vacancies.

Barnhill Poorhouse and Hospital.—Medical Officers (Two Male Assistants). Salary £90 to £100 per annum, with board, apartments, &c. Applications to Jas. R. Motion, Inspector and Clerk, Parish Council Chambers, 266, George Street, Glasgow.

Beverley Dispensary and Hospital.—Medical Officer and Dispenser (non-resident). Salary £160 per annum. Applications to C. J. Arden, Clerk.

Bradford Royal Infirmary.—House Surgeon. Salary £100 per annum, with board and residence. Applications to William Maw, Secretary.

County Asylum, Dorchester.—Second Assistant Medical Officer. Salary £140 and all found. Applications to the Medical Superintendent.

Dewsbury and District General Infirmary.—House Surgeon. Salary £100 per annum with board, residence, and washing. Applications to Charles J. Abbs, Secretary, Infirmary, Dewsbury.

Hospital for Sick Children, Great Ormond Street, London, W.C. Resident Medical Superintendent. Salary 100 guineas per annum, with board and residence in the hospital and £5 washing allowance. Applications to the Secretary.

London County Council.—Coroner for the South-Eastern District of the County of London. Salary £900. Applications to G. L. Gomme, Clerk of the Council.

London Hospital, Whitechapel, E.—Medical Registrarship. Salary £100 per annum. Applications to G. Q. Roberts.

Middlesbrough County Borough Asylum, Marton-in-Cleveland, Yorkshire.—Assistant Medical Officer. Salary £130 per annum, with furnished apartments, board, and washing. Applications to the Medical Superintendent.

New Ross Union, Carrigbyrne Dispensary District.—Medical Officer. Salary £125 per annum, together with the usual Vaccination Fees. Applications to P. A. Pope, Clerk of the Union.

Royal Hospital for Incurables, Donnybrook, Dublin.—Resident Medical Officer. Salary £120 per annum, with board and furnished apartments. Applications to John J. Thompson. (See advt.)

St. George's Hospital Medical School.—Secretary. Salary £150, with emoluments. Applications to the Dean.

Birth.

HASSALL.—On Nov. 19th, at Headingley House, Knutsford, the wife of John M. Hassall, M.D., of a daughter.

Deaths.

OLDHAM.—On Nov. 19th, at his residence, Cannington, Boscombe, Bournemouth, Henry Oldham, M.D., F.R.C.P., in his 88th year.

PRIOR.—On Nov. 18th, at 4, Goldington Road, Bedford, Amelia, the beloved wife of Charles Edward Prior, M.D., aged 77 years.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

VOL. CXXV. WEDNESDAY, DECEMBER 3, 1902. No. 23.

Original Communications.

SENILE CATARACT AND ITS TREATMENT. (a)

BY A. MAITLAND RAMSAY, M.D.,

Fellow of the Faculty of Physicians and Surgeons, Glasgow; Surgeon to the Glasgow Ophthalmic Institution; Professor of Ophthalmology in St. Mungo's College, Glasgow; and Lecturer on Diseases of the Eye in Queen Margaret College, University of Glasgow.

CATARACT, in medical acceptance, denotes an opacity of the crystalline lens or of its capsule, and this implies a classification of cataracts into lenticular and capsular, and a further subdivision of the former group into nuclear and cortical. Since the opacity must be in the lens, in its capsule or in both, this anatomical division has the advantage of including all forms of the disease, but clinically it has been found more convenient to refer to cataracts as hard, soft, or fluid; as white, amber, or black: as congenital, juvenile, or senile; as primary or secondary; as progressive or stationary; as mature or immature.

All forms of cataract depend upon three main factors—the anatomical position of the opacity, the age of the patient, and the condition of the eye. From the time of birth till about the age of thirty all lenticular opacities are cortical and soft: but after the third decade of life, the nucleus has developed so far that it acquires a predominating influence over both the consistency and the character of a cataract, while after the sixtieth year the lens becomes so hard that the cataract is spoken of as nuclear and senile. Under ordinary circumstances, therefore, the development of opacity may be looked upon as an incident due to the advance of years, and except for the loss of transparency in the lens the eye is physiologically sound.

In such a case the cataract is spoken of as primary, in contradistinction to the secondary one which appears in the course of some eye diseases, or after an eye injury. For example ophthalmia neonatorum sometimes leaves on the anterior capsule of the lens an opacity, due to inflammatory changes resulting from a central perforating ulcer of the cornea; or a cataract, characterised by rapid development and by a peculiar whiteness, due to inflammatory thickening of the capsule, may arise in choroiditis or in detachment of the retina; or, lastly, the lens may lose its transparency, and a cataract, secondary to pathological processes in the choroid, arise in high degrees of myopia. This last begins, as a rule, in the posterior pole of the lens, is usually brownish in colour, and takes many years to mature. A cataract is also at times spoken of as secondary to some constitutional disorder, the most familiar example being the opacification of the lens which occurs in the course of diabetes.

It is evident, then, that the subject of cataract is too wide for treatment in one lecture, so my remarks will meanwhile be limited to the diagnosis and treatment of the senile form of the disease. As a result of the advance of years the lens steadily undergoes a process of hardening or sclerosis which gradually increases the size and changes the colour of the nucleus. A lens in this condition possesses in considerable degree the property of reflecting light, and consequently the pupil of an elderly person has rarely the brilliant jet-black appearance presented in youth, but is generally dull and grey. This is what is known as the "senile reflex"; and it must never be confused with cataract, for though the lens is old and hard it has lost none of its transparency. The alteration is so far purely physiological, and it is usually very difficult to determine why in certain cases superadded pathological changes make their appearance and render the lens opaque. At first, after the diseased condition has shown itself, the cataract as a rule develops very slowly: for months and even years it may remain seemingly stationary, and then the opacity may, without any obvious cause, rapidly become complete.

The etiology of cataract cannot be associated with any special disorder of the general health, although, as has been said, the frequency of its occurrence in connection with diabetes mellitus has given rise to the term "Diabetic Cataract." A considerable percentage of cases are associated with albumin in the urine, and with the digestive difficulties and vascular changes which accompany renal cirrhosis. Heredity seems to play an important *role* in the causation, and the disease is often seen in several members of the same family, and can be traced back through successive generations. Senile cataract may occur any time after the fortieth year, although it is far more common in the aged. Statistics prove that certain occupations act as predisposing causes, and the most frequent sufferers are glass-blowers, blacksmiths, and those whose occupations necessitate the exposure of the eyes to strong heat and bright light.

One of the earliest premonitions is when a person who has been using glasses for reading finds that he can dispense with their assistance. Such a one usually puts his spectacles aside gleefully, saying he has got his "second sight," and can read his newspaper perfectly well with the naked eye; but he fails completely to connect this with the fact that he has now difficulty in recognising a friend on the opposite side of the street, and that vision for distant objects is not nearly so keen as formerly. As these changes are due to increased refractive power in the lens, which render the eye myopic, vision for distance may, at first, be improved by the use of concave glasses, but this can only be for a time. Another characteristic symptom is when a person complains that on looking at a bright light, such as the moon or a star, he sees it doubled or quadrupled. This monocular polyopia is also due to changes in the refraction of the lens, and as it causes the patient much annoyance, may lead him to complain of his sight before the slightest trace of cataract can be detected by means of the ophthalmoscope. Where the eyes have been overtaxed at fine work the first symptoms are usually eye-strain, accompanied by hyperæmia of the lids and ocular conjunctiva; and in these cases the patients often complain also of muscæ volitantes, describing the motes as moving with the eye and having at times a resemblance to a cloud of dust or a fine cobweb. The change once begun usually progresses, and as time goes on the transparency of the lens is interfered with more and more, until at length the pupil loses its blackness and becomes occupied by a cataract.

(a) A Post-graduate Lecture delivered in the Glasgow Ophthalmic Institution, November 11th, 1902.

As the opacity in the lens increases, the vision naturally becomes more and more indistinct, and in the final stages of the disease the patient is only able to distinguish light, and is quite unfit to walk about alone. The gait of a person in this condition is very characteristic; he walks slowly as if afraid to step forward, and holds one hand outstretched to feel his way, while with the other he tries to shade his eyes from the light. This attitude should be specially noted, because it is in such marked contrast to that of one who has lost his sight through atrophy of the optic nerves. The latter shows no sign of fear, but walks boldly onward with head and shoulders erect and looking straight in front of him.

The chief objective sign of cataract is the opacity. In the earliest stages this can be recognised only by means of the ophthalmoscope, although as the disease advances towards maturity it becomes quite plain to the naked eye. In all uncomplicated cases the iris presents a normal appearance, the pupils respond actively both to the stimulus of light and in the act of convergence, and the intraocular tension is not increased. A shallow anterior chamber indicates that the lens has become swollen owing to a rapid opacification of its cortex, but as maturity is approached the lens again shrinks and permits the iris to fall back into its natural position so that the aqueous chamber is restored to its normal dimensions.

When one is investigating a case of cataract it is always advisable that the various steps of the examination should be conducted in a definite order. Particular attention should be given to the patient's account of his symptoms, for much may thus be learned of the past history of the eye and the probable duration of the diseased condition, as well as of the state of his general health. The eye should then be examined carefully for any abnormality in the pupil or iris, for inflammation of the conjunctiva or of the edge of the lids, or for any inadequacy of the tear passages. The visual acuity should always be tested, although if the patient be already blind it will be possible to determine only his power of distinguishing and locating a light. The functional activity of the retina may be still further interrogated by gently palpating the sclerotic and noting the presence or absence of phosphenes.

The eye should afterwards be examined by oblique illumination and by the ophthalmoscope, the latter being of special value, as its use enables us, when the pupil is dilated, to detect not only the very beginnings of cataract, but also changes in the fundus oculi, more especially when these are situated in the periphery or in the macular region. Moreover in a case where the sight is dim and the pupil hazy, ophthalmoscopic examination will prevent the terrible blunder of allowing a patient to become hopelessly blind from glaucoma, while an imaginary cataract is supposed to be slowly maturing.

Even when the existence of cataract has been distinctly made out, the surgeon should give a very guarded prognosis as to the length of time it may take to ripen. As a rule the complete opacification of the lens requires from two to three years; but during its passage through the incipient and progressive stages many a cataract remains stationary. This is very often the case where it is complicated by myopia, and in the aged a lenticular opacity may not increase for years. In many cases, indeed, the progress is so slow that the stage of maturity is never reached. One of my patients, a gentleman between seventy and eighty years of age, used to tell me that though he had been informed, twenty years before, that he had cataract in both eyes, and that he would be blind in two years, his sight had never become any worse. To say that a person with a few opaque striæ in the lens is suffering from cataract is no doubt perfectly true, but the use of the word at this early stage is apt to convey a false impression and create much unnecessary alarm. Many a patient would, after hearing such a diagnosis, live in constant dread of the onset of blindness which might never come.

While a cataract may be said to be optically ripe when the vision is reduced so far that the sufferer is unable to distinguish the knife and fork on his dinner plate, it may not then be surgically ripe; and it is important to wait, if possible, for the latter stage before operating, because then the extraction will be more complete. The degree of maturity can always be estimated by sharply illuminating the edge of the pupil and observing the breadth of the shadow cast by the iris. When the whole cortex is opaque the iris lies closely against the cataractous surface, and does not form a shadow when a light is held against the eye. Whenever the anterior chamber has regained its normal depth, and there is no shadow, the cataract is said to be surgically ripe.

A patient suffering from cataract, however, requires help in the early stages. Unfortunately, there is no means known whereby an opaque lens can be rendered transparent, but during the period of waiting till surgical operation becomes possible the sight may be improved by the use of mydriatics if the opacity be central, and of myotics if it be largely peripheral. Many aged persons with nuclear cataracts are enabled to see satisfactorily if they bathe the eyes daily with a very weak solution of atropine. Frequently also concave glasses give relief for a time. All patients should be cautioned against overtaxing the eyes by struggling to see small print, or to do fine needlework, and they should avoid, as far as possible, the exposure of the eyes to bright light and strong heat. In every case attention must be paid to the state of the general health and means taken to ensure the efficient action of bowels, kidneys, and skin, and to maintain nutrition as a whole at the highest possible level. Whenever the patient's sight becomes so defective that he has difficulty in following his usual occupation the question of surgical interference must be considered, and though it is always preferable to delay operation until the cataract is mature a patient ought in no case to be permitted to become blind. When both eyes are equally affected one ought to be operated upon whenever the patient experiences difficulty in carrying on his work. It may then be necessary to perform a ripening operation a few weeks before extraction is attempted. Under such circumstances I am in the habit of making an iridectomy, and then applying massage directly to the capsule of the lens with a small spatula. It is, however, usually quite safe to extract a cataract before the stage of maturity is reached, but as, in that case, a considerable quantity of cortical matter is necessarily left in the eye, the process of healing is apt to be complicated and demands much skill and care on the part of the surgeon. Before any operation is undertaken the field of vision must be carefully tested with a light in order to determine, as far as possible, that there is no atrophy of the optic nerve or detachment of the retina. The presence of either of these lesions would obviously render the operation of no avail in restoring sight. Careful examination must also be made to negative the existence of chronic conjunctivitis, or of blenorrhœa of the tear passages, and in all doubtful cases there should, without fail, be a bacteriological examination of the fluids in the conjunctival sac. If pyogenic micro-organisms are present there is great danger that after operation the eye will be lost from suppuration.

Wherever possible, a patient should be placed in charge of a competent nurse at least forty-eight hours before the time fixed for the operation. He should have a warm bath, put on clean under-clothing, and go to bed. The nurse must report if there be any cough, sickness, or unusual restlessness or nervousness. Early the following morning a purgative, preferably a half to one ounce of castor oil, is administered, to make sure that the bowels will be freely evacuated. The heart, lungs, and urine should be examined. Twenty-four hours before the operation, the face, the surface of the closed lids, the eyelashes, and the eyebrows should be washed with hot water, in which 1 per cent. of carbosapol has been dissolved, and be thoroughly scrubbed with a moderately hard nail-brush. While this is being done the eyelids must be kept tightly closed to prevent any irritation of the conjunctiva. After all the soap has been washed away with hot sterilised water, the conjunctival sac is douched with warm saturated solution of boric acid, special attention being given to the outer and inner canthus and the edges of the eyelids. On the morning of the day of operation the eyelids and surrounding skin are again thoroughly washed and the conjunctival sac douched, every detail of the process, except the scrubbing with the nail-brush. being as carefully attended to as on the previous day. Female patients should have the hair divided and put into two plaits in order to prevent it from becoming matted or entangled in the bandage. On the day itself the patient must not be allowed to eat heartily, and the food itself should be light and easy of digestion. Whenever it is practicable the time chosen ought to be the morning, shortly after the patient has awakened from sleep. For at least an hour before the operation the eyes are kept covered by a compress soaked in a solution of perchloride of mercury, 1 in 5,000, and this should remain in place until it is removed by the surgeon. Half an hour before, 30 grains of bromide of potassium, or teaspoonful of bromosoda, should be administered. After the patient is on the operating table the perchloride dressing is removed, a towel is adjusted like a turban round the head, and a mackintosh covered by a towel is spread over the chest and tucked closely round the neck. All instruments and dressings must be thoroughly sterilised, and the hands of the surgeon and of his assistants rendered aseptic.

Of all operations for the removal of a cataract simple extraction is by far the most perfect, and when successful leaves nothing to be desired. Unfortunately, however, in a considerable percentage of cases a prolapse of the iris occurs within a few hours of the operation and causes difficulties and dangers, all of which may be avoided by performing an iridectomy either at the time of the extraction or a few weeks in advance of it. The preliminary iridectomy has many advantages. It helps to ripen the cataract, and allows the iris time to heal before being pressed upon and bruised by the lens during its escape from the eye, and it tends to equalise the intraocular tension, and thereby diminishes the risk of choroidal hæmorrhage, so that almost all authorities are agreed that it is preferable when patients are old and feeble or have only one eye. Notwithstanding the increased safety, however, which the preliminary iridectomy affords, patients shrink from being operated on twice, and so, if there be no complications, it is the combined operation that is the most frequently performed.

The instruments required are a speculum, a Graefe linear section knife, iris forceps and scissors, a cystotome, a curette, and a small spatula. The knife should be fresh from the cutler, and, after its edge and point have been carefully examined and tested, should, just before being handed to the surgeon, be dipped for a moment in boiling water, and afterwards cooled in a bath of sterilised water. After the eye has been bathed with a warm saturated solution of boric acid, and anæsthetised by a 2 per cent. solution of cocaine, the lids are separated by the speculum, the limbs of which are extended to their utmost capacity and then firmly clamped with a binding screw. The patient is instructed to look downwards, and the surgeon, if he be not ambidexter, stands behind him for the right eye and in front of him for the left. The blade of the knife is laid gently across the cornea in order to satisfy the patient that the eye has been rendered thoroughly anæsthetic. A puncture is made, perpendicular to the surface of the cornea, and exactly in the corneo-scleral margin in a line with the upper border of the pupil, and the handle of the knife is depressed until the blade lies parallel to the surface of the iris. It is then carried slowly across the anterior chamber to a corresponding point on the opposite side where the counter-puncture is made. The knife is now pushed slowly through the cornea, right up to the hilt if possible, but care must be taken that the point does not come into contact with the skin at the inner canthus. The section should be wholly in the corneo-scleral margin, and is completed by two or three sweeps. It should not be any larger than necessary, but should always be big enough to permit the lens to escape easily. The forceps are then introduced through the wound, the iris seized at the pupillary border, gently pulled out of the eye, and excised by a single snip of the scissors. The cystotome is now passed into the eye and directed downwards to the lower border of the pupil. Its cutting edge should be turned towards the lens and the capsule freely ruptured by an incision from below upwards. At this stage the speculum should be removed, and if there be any bleeding from the iris, the blood should be washed away by douching with warm boric acid solution. The lens can now be extracted by pressing on the lower lid by the thumb of the right hand, and on the upper by the forefinger of the left. If any cortical matter remain it should be pressed out by means of a curette, but as a rule digital manipulation is sufficient to remove the whole lens, leaving a jet black pupil. The "toilet" of the eye must now be attended to. If the iris be prolapsed it should be carefully replaced by the spatula, and the lips of the wound left in accurate position. After the lens is removed the patient ought to be able not only to count fingers but to distinguish one from the other.

When the operation is complete, the eye is again bathed with the boric solution, the eyelids wiped dry with a pledget of absorbent cotton wool, and covered by an oval-shaped gauze dressing spread with freshly prepared Martindale's No. 2 boric ointment. Over this are laid several layers of absorbent wool, care being taken to fill up the hollow at the inner canthus so that there will be no unequal pressure upon the eyeball. The dressings are retained in position by a net bandage, which covers both eyes, and which is secured by tapes tied behind, above the head, and below the chin. The patient, after being warned to make no exertion, is carried to his bed, which has been comfortably warmed by hot-water bottles, the temperature of the room being about 60° F., and all light excluded. He is laid on his back and told to keep his head as still as possible, and not to rise or get out of bed for any purpose whatever.

Of the accidents which may occur in the course of an operation the chief are:—1. Premature escape of the aqueous. When this occurs it is not possible to carry the knife across the anterior chamber without wounding the iris. The knife should therefore be withdrawn, the eye bandaged, and the operation postponed until the aqueous has had time to reaccumulate. 2. The iris may fall in front of the knife. When all efforts to disengage the iris are unsuccessful, the edge of the blade should be turned slightly forwards, so that a piece of the iris may be excised during the completion of the section. The piece of iris thus cut off should be picked out of the eye with forceps, and the coloboma forms the iridectomy. 3. Escape of vitreous. This is a much more serious matter, and is always to be feared when the patient is nervous and unsteady, when the corneal section is too small, or when the vitreous is fluid. When the escape occurs before extraction, the lens is apt to slip backwards and pass out of sight, so that the surgeon may fail to remove it. If, on the other hand, the escape follows the extraction, a small loss of vitreous is not of much moment; but whenever the loss is large there is always the danger that sooner or later detachment of the retina will occur. 5. Hæmorrhage from the choroid. Happily this is a rare accident, but when it does occur the eye is hopelessly ruined. Usually it comes on without warning. The operation may have been completed successfully, when all at once the patient cries out with pain, and blood escapes through the wound in sufficient quantity to saturate the dressings. In some cases the eyeball retains its shape, but more frequently it shrinks and requires to be enucleated, partly to get rid of pain and partly lest it should excite sympathetic inflammation of the fellow-eye.

For at least forty-eight hours after the operation the nurses must keep the patient under continuous observation, see that he lies still, and be particularly watchful that the bandages are not disturbed. They should report at once if there be much restlessness, coughing, delirium, retention of urine, or complaint of pain, but never under any circumstances should they administer either stimulants or narcotics unless these have been specially ordered. If all goes well the eyes are dressed on the second day, every care being taken to keep the parts aseptic. The lids are wiped by a piece of gauze and then gently separated, so that the wound may be examined. If by this time the anterior chamber has not reformed it is probable that there is a piece of capsule or conjunctiva between the lips of the wound, and that in consequence the process of healing will be much delayed; but as eyes in which the incision heals slowly rarely suppurate, this complication need cause no alarm. A single drop of a solution of 1 per cent. atropine and 2 per cent. cocaine is instilled; a dressing similar to the one removed applied, and the eyes thereafter bound up for twenty-four hours. More light is now allowed to enter the room, and on the third or the fourth day the dressings are again removed, the eye examined, and, if the pupil be not dilated, another drop of atropine and cocaine solution is instilled. The eye which has not been operated upon may now be left unbandaged, but it is to be protected from the light by a large brown paper shade, or preferably by a pair of protective London smoked glasses. On the fourth day the patient is allowed to sit up in bed for meals, and if there be no sign of inflammation, to leave bed on the ninth day.

At first the dietary should consist largely of liquids so as to avoid as far as possible the movement of the jaws during the act of chewing. On the fourth day some mince-meat and potatoes may be added, and if there be no unfavourable symptoms the patient may be allowed to feed himself. If the bowels have not acted a laxative is given early in the morning of the fourth day.

After successful extraction of the cataract the patient is not able to see clearly until he is provided with glasses equivalent to the lens which has been removed. It is not wise, however, to allow him to use spectacles until six or eight weeks after the operation, and he should be warned to be very careful in the use of the eye for several months. Quite a large percentage of patients regain normal vision, but the good results naturally expected are occasionally spoiled through complications that occur during healing. One of the simplest but most troublesome of these is inversion of the lower lid. Usually the entropion disappears of itself, but in case of difficulty it may be rectified by the application of collodion to the skin of the lid, or the edge of the lid may be pulled outwards by a strip of sticking plaster. The great majority of cataract extractions are followed by inflammation of the iris, but as a rule this is so slight that it need cause no alarm. When, however, there is a large amount of cortical matter, the exudation from the iris becomes mixed with the lenticular substance and seriously interferes with its solution. As a consequence a tough after-cataract remains, and before the patient can regain his sight this requires to be removed by operation. Iritis is always to be feared when, after the first dressing, arthritic foam is seen at the outer and inner canthus, since this may be regarded as a danger signal indicating that the patient has rheumatic or gouty tendencies. In these cases the inflammation may not confine itself to the iris, but may also involve the ciliary body. Severe irido-cyclitis is always followed by a closed pupil. Usually this can be remedied and sight restored by a subsequent operation, but in some cases—more particularly if the dressings have been disturbed, and the eye thereby injured, or if the patient suffer from chronic disorder of the stomach or bladder—the lens matter assumes a yellowish colour, the conjunctiva becomes thickened and velvety, and the eyeball is tender on pressure. There is then great danger that the intraocular tension will become lessened, and that ultimately the eyeball will shrink. If any capsular matter, or a tag of the iris, get entangled in the corneal wound, iridocyclitis is sometimes accompanied by increase in the intraocular tension. This is a very grave complication, and unless relief be speedily obtained sight will be lost from subacute glaucoma. Under these circumstances a broad needle should be passed through the cornea, and made to perforate the structures shutting off the aqueous from the vitreous chamber. When these are freely divided the normal intraocular circulation is restored, and the imminent danger from glaucoma averted.

If post-operative hæmorrhage be excluded, the most dangerous after-complication is suppuration. The introduction of antiseptic methods, and the care now taken of patients both before and after operation, have done much to diminish the risk, but in spite of everything a number of eyes are still lost by septic infection. The inoculation is almost always due to micro-organisms that have been lurking in the conjunctival sac. They are probably always present, but become able to work mischief only in unhealthy subjects, and especially in those whose tissues have been rendered easily vulnerable by alcoholic excesses and want of proper nutriment. Infection takes place all the more readily if, during the exit of the lens, the cornea has been bruised, or if an escape of vitreous has taken place.

The lens and vitreous are most favourable culture media for pyogenic micro-organisms, and so suppuration, once started, pursues its course practically uninfluenced by any form of treatment. In my own experience of such cases I have found that the application of local antiseptics, or the use of the cautery, avails but little: and that the only chance of saving an eye after suppuration of a corneal wound lies in keeping the parts thoroughly clean by copious douching with sterile saline solution, and by the judicious administration of quinine and stimulants. In every case where there is a history of inflammation of the conjunctiva, and where suppuration is to be feared, the secretions ought to be examined for bacteria, and as long as any dangerous organisms - more particularly the streptococcus, the staphylococcus albus or aureus, the diplococcus (pneumococcus), or the bacillus coli—are present, operation should not be attempted.

Prior to the days of aseptic treatment the cases of cataract extraction lost through suppuration were, as now, those in which there had been previous inflammation of the conjunctiva or tear passages, or in which the patient's vitality was low. The tissues could heal in spite of the micro-organisms present in the conjunctival sac; but where these were in abnormal numbers and pyogenic, or where the vulnerability of the tissues was greater, the eye could not be saved. Antiseptic methods have done much to diminish the frequency of disaster in the former group by destroying the germs or lessening their number, but the liability to failure in cases of the latter kind remains as before; and the necessity for action along this line suggested by clinical observation is borne out by the results of theoretical and experimental research so ably dealt with in Professor Welch's recent Huxley Lecture.

"The struggle," says Dr. Welch, "between the bacteria and the body cells in infection may be conceived as an immunising contest, in which each participant is stimulated by its opponent to the production of cytotoxins hostile to the other, and thereby endeavours to make itself immune against its antagonist." When the body is healthy it possesses the power of producing substances specifically antagonistic to all sorts of micro-organisms, but with this power any morbid state at once interferes; and as in all infections, whether local or general, "abnormal metabolism is an essential condition," patients of low vitality will be in such a state that the substances produced may be not only not antagonistic to parasitic organisms, but actually stimulating to their growth.

This being so, one must not only endeavour to render the field of operation sterile, but must also devote the utmost care and attention to what is of equal importance —the physical condition of the patient himself. For some months before the operation he must be well fed, and kept as much as possible in the open air; and a course of salines with iron and quinine is usually attended with the happiest results. Rest and preparation are necessary in every case, no matter what may be the sufferer's position in life, but should he be one who has been, owing to defective eyesight, unfit for work for several months, and through poverty unable to procure a sufficient amount of food, he will require special care, since not only will he be in a condition unfavourable for the rapid healing of any wound, but he will also have tissues vulnerable to the slightest infective taint, and suited for the rapid spread of suppuration. While, therefore, every effort should be made to render the field of operation free from micro-organisms, care should equally be bestowed on the state of the patient himself, especially if he be poor and habitually ill-nourished. Were more attention paid to the health of those broken-down subjects prior to cataract operations the number of failures from suppuration would be very considerably reduced, and it is only by care that this much to be desired result can be attained.

SOME DISEASES SIMULATING ACUTE RHEUMATISM, AND THEIR PROBABLE RELATION TO CHRONIC RHEUMATOID ARTHRITIS (*a*)

By CHARLES J. MACALISTER, M.D. (Ed.), M.R.C.P.

Physician to the Royal Southern Hospital, to the Home for Incurables, and to the Country Hospital for Children.

It was my privilege some years ago to give a lantern demonstration at the medical institution, illusting the clinical features of chronic rheumatoid arthritis, and of a number of other conditions which are sometimes mistaken for that disease. On the occasion of that demonstration I directed attention to a circumstance which is interesting and probably important, when considered in conjunction with the experiences culled from cases such as those about to be related. I refer to the fact that many of the cases in which the chronic deformities had taken place, and had progressively become worse—rendering the patient at last crippled and helpless—began with symptoms similar to those which I am about to detail as characterising some of the diseases which simulate acute rheumatism. In other words, these patients have told me that their illnesses began with very protracted attacks of "rheumatic fever," which resisted all treatment and gradually merged into the condition of arthritic deformity, which they regard as chronic rheumatism.

I have had several opportunities of watching these protracted cases of so-called rheumatic fever, and have seen them undergo a, sometimes rapid, transition into classic examples of rheumatoid arthritis, and, to me, it seems evident that these initial rheumatic attacks are not, properly speaking, rheumatic in their nature at all, but that they constitute the acute phase of what will ultimately become chronic rheumatoid arthritis, unless the cause can be found and removed, as it sometimes may be.

A reference to any series of statistics bearing upon the treatment of acute rheumatism with the salicylates, elicits the fact that a small proportion of the cases are little, if at all, influenced by this means of treatment; the fever goes on for weeks and weeks and the pains and sweating remain, so that it is considered that there are cases of rheumatic fever which resist the action of the specific remedy. From my own observations—which have been carefully directed to this point during the past few years—I have concluded that these resisting cases are not rheumatic fever, their clinical histories are different, as well as their relation to the salicylates, and they are evidently the result of a totally different toxin, the source of which can sometimes be traced and at other times it cannot. In some cases we are able to say that some part of the nasal, respiratory, or gastro-intestinal mucous membrane has been the seat of absorption, and it is more than probable that one of the reasons for the prevalence of the chronic disease in women depends upon the absorption of the poison from some part of the genital tract, to which far too little attention has been paid in this relation, considering that a large number of the patients themselves associate the onset of chronic rheumatoid arthritis with disorders of these parts. Regarding the specific action of the salicylates in rheumatic fever, I have been so impressed with my own almost invariable experience that true rheumatic fever quickly subsides under their administration, whereas the resisting cases so frequently prove to be non-rheumatic, that I have come to think that no true cases of rheumatic fever are uninfluenced by them.

In the course of the years 1900-01 fifty-two cases were admitted under my care at the Royal Southern Hospital, registered as rheumatism in one form or another (excluding cases of established rheumatoid arthritis); of these, thirty-seven were undoubted cases of acute rheumatism, three proved to be early cases of rheumatoid arthritis, and six were indefinite. The remaining six cases are those worthy of note on account of their similarity to rheumatic fever in some of their clinical features, while they differ from it not only in this resistance to the action of the salicylates, but also in their presenting no liability to cardiac complications, and in some other particulars which shall be referred to incidentally. It is not possible to show the temperature charts, but it may be mentioned that in these toxic conditions the temperature is remittent, the remissions being in the mornings and the exacerbations in the afternoons and evenings. The joint pains tend to be symmetrical, and to spread to new joints, without leaving those already affected, *i.e.*, they do not flit about as in acute rheumatism. The temporo maxillary and cervical joints are often affected, and the small joints of the hands and feet, and the sterno clavicular articulations are not unfrequently attacked as well as the larger joints.

Case I.—C. W., labourer, æt. 40, admitted September 18, 1901, complaining of pains and swellings of the joints of both upper and lower extremities, which began fourteen days previously. No previous illnesses. Ascribed present condition to getting wet. There was headache and profuse sweating, swellings of knuckles of both hands and tenderness in the finger joints. Wrists, elbows, and shoulders very painful; right ankle swollen, and pain in both ankles extending up to the knees. Heart sounds all closed, but very faint (emphysema). Lungs normal; urine, sp. gr. 1018; acid; no albumin.

Sept. 18th.—He was given 15 grs. sodium salicylate every four hours, but the temperature, which was remittent in type (99·0° a.m. to 101° p.m.) tended to be higher in the evenings during the next few days. The nasal mucous membrane was normal, slight discharge of mucus. On September 22nd, boric acid insufflations were ordered in addition to the salicylate.

Sept. 25th.—There being no improvement, the fever continuing, and the pains and redness having involved the right sterno clavicular joint, the salicylate was omitted and guaiacol carbonate (10 grs., four times daily) substituted. This was not followed by any benefit.

Sept. 28th.—A draught containing hydrochloride of quinine 4 grs., with phenazonum 10 grs., was now given night and morning, and subsequently three times a day. The temperature fell by lysis, becoming normal on October 1st, after which date it did not again rise above the normal line.

There was corresponding improvement in the general conditions, the pains and swellings being entirely gone by October 4th. Concomitantly with this improvement, patient commenced to eliminate with the perspiration some volatile matter, which had a strong garlic-like odour. It was so offensive that he had to be removed from the ward (the sweat did not blacken lead paper). The elimination of this matter was assisted by the administration of infusion

---

(*a*) Contributed to the Reports of the Royal Southern Hospital, Liverpool.

of jaborandi, and it had ceased by about October 22nd. He left the hospital perfectly well on October 25th.

In this case, the source of the infection was not certain; but it was probably gastro intestinal. The elimination of the garlic-smelling material had evidently something to do with the recovery, which so rapidly followed the administration of the quinine and phenazonum.

Case II.—J. L., æt. 26, admitted July 31st, 1901. previous rheumatic attacks, viz., fourteen years ago and six years ago. Present illness began seven days ago with headache, sweating, pains and much swelling of knees, toes, elbows and shoulders. On admission slight swelling and redness and severe pains in these joints, and also in the finger joints. Sweating freely—perspiration sour smelling. Miliaria over chest and abdomen. Tongue thickly furred. Bowels constipated. Respiratory system normal. Heart sounds normal. Pulse 90, regular, full volume. Low tension. Spleen, ninth rib to costal margin.

He was at once ordered 10 grs. sodium salicylate every three hours, but at the end of a week this had not influenced the temperature, which ranged from 99 6° in the mornings to 101·2° in the evenings; in fact, on August 5th, 6th, and 7th the temperature had become higher each night, and the pains were as severe as ever, especially in the right elbow and shoulder, and the knuckles had become red and swollen. The sterno clavicular articulations too had become swollen and painful.

On August 7th guaiacol carbonate was substituted for the salicylate, but on the 10th the temperature was still high, 101·4, and the left temporo maxillary articulation had become involved. There was profuse perspiration; the skin covered with miliaria. On this date it was observed that the secretions from the nose were bloodstained. The guaiacol was stopped, and five grains of sulphate of quinine with 30 m. dilute hydrobromic acid ordered at four-hourly intervals for four doses. The nose to be washed out frequently with a lotion containing one drachm of liquor hamamelidis in an ounce of a saturated solution of boracic acid.

On August 11th the evening temperature was 99 6°, and during the daytime it was subnormal, and after August 12th it remained normal.

The pains rapidly subsided, and had gone by August 16th, and there was corresponding cessation of the sweating, and general improvement.

On August 29th there was some return of the pains in the hands, and the temperature registered 100° in the evening. This was found to be due to a small glandular abscess in the right axilla, on relief of which the patient made an uneventful recovery. The treatment of the nose was continued until his discharge on August 29th, 1901.

The seat of absorption was in this case a chronic rhinitis.

Case III.—P. D., æt. 38, labourer, admitted April 3rd, 1901. No previous illnesses, no syphilis. Had a rheumatic attack fourteen years ago, and has had three similar attacks since, all characterised by pains in joints. Present attack commenced three weeks ago with severe pains and swellings in right elbow and wrist, and both knees, which persist. and he has, in addition, pain and tenderness in joints of fingers. Sweating. Temperature on admission, 101°. Cardiac sounds closed, somewhat muffled by emphysema. Three days ago left eye became inflamed. He is subject to these attacks of catarrhal ophthalmia. Injection of sclera, marked chemosis. Bowels moved every second day. Liver normal.

He was given sodium salicylate and sodium bicarbonate, of each grs. x. every four hours, and on April 5th the temperature was normal. Systolic impurity at cardiac apex. The pains did not disappear with the subsidence of the temperature, and on April 7th gr. 5 potass iod. with grs. x. sod. bicarb. was substituted for the salicylate and the pains gradually subsided (recurring in intensity from time to time) until May 1st, when some slight soreness remained in the elbows. At this time the conjunctivitis spread to the right eye (left had not recovered), which became intensely inflamed, and on May 3rd there was some iritis of this eye. From May 5th to 10th there was recrudescence of pain in elbows and hands, the latter being much swollen. The temperature during these days was remittent in type, 99·2° in morning to 101·6° in evening, there being a lysis till May 12th, when it became practically normal; on May 18th the fever returned in similar type and continued until June 9th, when for the first time it did not exceed 99·4°. Thereafter there was no rise above 99·2° until June 22nd, when it became normal and remained so. During the whole of this time the rheumatoid pains were severe, there was profuse sweating and the symptoms were quite unrelieved by salicylates given alone, with colchium, bicarbonate of sodium, and with cimicifuga. Nothing, in fact, either locally or internally, did any good until June 8th, when quinine sulph. gr. v. with acid hydrobromic dil. m. xxx., was given three times a day with most beneficial results as regards the fever, and the acuteness of the pain was relieved. Some stiffness remained in the left ankle and shoulder, and in a finger of the left hand; these joints were painted with guaiacol and tinct. iodi. and eventually recovered completely. On July 1st there was slight return of pain and some stomach disturbance; July 3rd, vomiting, followed by diarrhœa, and the temperature rose to 104·2°, falling to normal next day. He was given sulphocarbolate of soda grs. x. with subnitrate of bismuth grs. xv., every four hours, and a Dover's powder to stop diarrhœa. He gradually recovered, and left cured on July 24th.

The condition probably resulted from a gastro-intestinal toxin.

Case IV.—R. P., tailor, æt. 20, admitted August 27th, 1900. Had an attack of rheumatism in both arms and legs two months ago. Eyes also inflamed at the time. Five days ago got a wetting, followed by severe pains in the left shoulder, right knee, right index finger, left shoulder and back of neck. He also started inflamed condition of eyes. No cardiac lesion. There was severe pain in eyes—slight iritis, and photophobia. This condition cleared up, under atropin, by September 12th. Shortly after admission it was found that he had a pustular eczema of the scalp, with many crusts. The hair was cropped, antiseptic fomentations applied until crusts all removed, then a suitable ointment.

The temperature was remittent in type, varying between 90° in the mornings and 101° in the evenings, until September 5th, after which it never exceeded 99°, but the pains and stiffness remained until after September 18th. After September 23rd the temperature remained normal, and recovery was uninterrupted. Bowels regular throughout.

Salicylates were given until September 20th. The fever was well marked until September 5th (ten days of treatment), subfebrile condition (99°—99.2°) until September 23rd, corresponding with disappearance of pains and stiffness in joints and with the removal of pustular discharges from the head, the temperature did not become normal to remain so until September 23rd, three days after all salicylates had been omitted.

Case V.—Malaria like Rigors.—Rheumatoid Pains in Joints.—Nasal Ulcer.—J. L., æt. 21, Russian sailor, admitted August 31st, 1901 (speaks English badly, gathered that he had been ill for some weeks), complains of pains in the joints of right arm and leg, very slight tenderness on pressure over the joints of these limbs, but no visible swelling; heart and lungs normal. All the extremities are cold, notwithstanding the warm weather. Nervous system excitable, exaggerated reflexes both in arms and legs. Knee and ankle clonus on both sides. He was given nitrite of soda gr. 1, and sp. ætheris nit., m. x. thrice daily. No rise of temperature occurred, and he slept and ate well until September 15th, when he had a rigor at one p.m., and the temperature rose to 103°. It rapidly fell to normal. September 16th, rigor and temperature 105° at one p.m. September 17th, rigor and temperature 103·6° at one p.m. September 18th, rigor and temp. 103·8° at ten a.m., the temperature remained high until one p.m., when 4 grs. quinine were given every four hours, and after this there was no further rise of temperature. The question of malaria was investigated. Nothing could be discovered in the blood, and the pain in the joints (which became slightly swollen), was not suggestive of malaria. A thorough examination revealed nothing either in the chest or abdomen to account for the rigors, but on the septal side of the right nostril an abrasion of the mucous membrane was noted, and some blood-stained mucus escaped from this side of the nose. The nostril was plugged with boric wool dipped in boric acid solution, at intervals of an hour. September 26th, quinine was given gr. 1, with nitric acid, thrice daily. September 30th, a dry pleuritic rub (no fever) appeared over the hepatic region of the right chest; this disappeared after application of a blister on October 3rd, when iodide of potassium was given thrice daily; after this, recovery was uninterrupted.

Case VI.—Alfred S., æt. 18, admitted April 8th, 1902, suffering from necrosis of right tibia (under care of Mr. Newbolt). April 22nd, operation. He did well, wound healed and temperature remained normal until May 24th, when he began to suffer from pains in knees and shoulders, and subsequently his wrists, knuckles, finger joints, elbows, ankles and toe joints all became swollen and intensely tender He had sweatings and remittent temperature. Salicylate of soda was given, but by June 7th no improvement having taken place, the temperature varying from 100·2° in the mornings to 104° in the evenings, 5 gr. doses of sulphate of quinine with M.30 of dilute hydrobromic acid were ordered to be given three times a day. He was placed under my care on June 12th. The operation wound was healed, and no breach of surface was found externally. On examining the nose the mucous membranes of the right nostril were seen to be swollen, redder than normal, and in contact. There was much sticky secretion between the opposed surfaces. The nose was ordered to be thoroughly disinfected four times a day with a powder consisting of hydrochlorate of morphia gr. 1, bismuth subnitrate 2 drachms, and acid boracic to 1 ounce. The temperature immediately began to subside. June 15th, pains much improved. Owing to want of care and perseverance in the treatment, which the patient at first resented, saying that "he did not see what his nose had to do with rheumatism," there was a temporary relapse, but after pressing the nasal disinfection the whole condition cleared up. The temperature became normal, the pains and swellings disappeared, and convalescence was speedily established. The heart in this case became dilated, and there was for a time a suspicious systolic murmur, which eventually cleared up entirely. It is interesting to note that the quinine with hydrobromic acid, which had proved so efficacious in cases apparently of gastro-intestinal origin, proved unavailing in this case, and it was only after the local source of infection had been attacked that relief was secured.

It must be noted, that attention was first directed to the nasal cavity as a seat of toxic absorption by Dr. William Carter, and it was in consequence of having read his address given to the Birkenhead Medical Society, on March 9th, 1894, that I came to examine the nose carefully in these rheumatoid cases.

PAROXYSMAL TACHYCARDIA ASSOCIATED WITH EPILEPSY. (*a*)

By R. TRAVERS SMITH, M.D., F.R.C.P.I.
Visiting Physician to the Richmond, Whitworth, and Hardwicke Hospitals, Dublin, &c.

K. M., a healthy-looking well-developed girl, æt. 14, was brought to the Whitworth Hospital by her sister on September 26th of this year (1902). She complained only of violent and rapid beating of her heart On feeling her radial artery the pulse was found frequent beyond counting, small, thready, and compressible. Auscultation of the heart revealed the astonishing rapidity of 248 beats per minute. My resident pupil, Mr. Tighe, independently confirmed this observation at the time. Except for its rapidity an impulse somewhat diffuse, and rather short, sharp sounds, the heart appeared normal. Nothing was noticed elsewhere other than a *distrait* and somewhat vacuous facial expression. At the girl's own request I allowed her to return home, having first made arrangements for her admission to hospital in the afternoon. On her arrival at home, and after this paroxysm of tachycardia had ceased, though she had some vague recollection of having been brought to a hospital in the morning, she did not remember the details of our interview, and the news imparted to her by her sister that she was to become an inmate of the hospital in the afternoon, caused her surprise and consternation. This circumstance well illustrates the lapses or partial lapses of memory accompanying many of the paroxysms of tachycardia in this patient, of which further evidence was subsequently adduced. The night of her admission she again complained of "an attack of the heart," when Dr. Holden, the house physician, was able to count her heart beats at 260 per minute.

The following personal and family histories were obtained from the patient herself and her relatives. K. M. had always been healthy till a year ago, when, in school one day, she suddenly became weak and her heart beat violently. The next "heart attack" as she called them, did not supervene for three months, from which time they increased in frequency till for some months before admission they occurred every two or three days, sometimes even twice daily. These "heart attacks" would come on absolutely suddenly without apparent cause, last varyingly from five minutes to four hours (commonly one or two hours), then as suddenly vanish. In these attacks she would be conscious of the great rapidity of her heart's action, but would make no further complaint. Her relatives (as well as the patient herself) recognised the impairment of memory which accompanied these paroxysms of tachycardia, and stated that on two or three occasions it amounted to a state of unconsciousness, in which she fell to the ground but did not convulse. Abundant passage of urine after her paroxysms was noted by the patient. Six months after the first appearance of these cardiac symptoms she began to suffer from seizures, of what I presume to have been minor epilepsy. Without warning she would suddenly lose consciousness for a minute or so, as well as she could judge. During that time she

---

(*a*) Read before the Medical Section of the Royal Academy of Medicine of Ireland, on November 21st, 1902.

would be absolutely oblivious to her surroundings, stop what she was doing or saying, then recall herself to consciousness with an effort. On these occasions she experienced nothing abnormal in her heart, in fact, looked upon these "attacks of giddiness," as she called them, as something entirely different from her "heart attacks." They never became as frequent as the latter, occurring only once a week approximately.

The opinion that these "heart attacks" were genuine paroxysms of tachycardia was strongly confirmed by the testimony of the patient's stepmother, a trained hospital nurse, who recognised the extreme rapidity of the pulse.

K. M.'s family history is of interest. She is the youngest of eleven children, four boys and seven girls. Her mother died from an unknown cause. Her maternal grandmother, herself healthy, had three sisters, all of whom were healthy, all of whom married, and each had one child. These three children, first cousins of K. M.'s mother, were all epileptics, one of whom became insane. This history indicates a decided neuropathic taint on the maternal side of K. M.'s family.

During the first of the seven weeks' residence in hospital K. M. had several severe paroxysms of tachycardia, and, as well, two seizures of major epilepsy, separated from one another by an interval of three days. These two fits appeared without premonition, the patient suddenly becoming unconscious and convulsing in the face and limbs. The convulsions passed off in a few minutes, save for an occasional twitch of the facial muscles, but the patient still remained in a state of coma for nearly an hour in the first, for fifteen minutes in the second. The pulse rate was up to 100 and to 96 respectively in the two fits. On recovery from both drowsiness and marked irritability were observed.

It may be stated at this point that repeated examinations made during the stay of the patient in hospital, except on the occurrence of the two fits or paroxysms of tachycardia, revealed nothing abnormal in the heart or elsewhere save an occasional functional systolic murmur most audible in the pulmonary area. The girl was bright and intelligent, with normal pulse and healthy apparently in every respect. The menstrual periods were not established. In short, observations made in hospital merely corroborated the patient's own statements.

After the second fit at the end of the first week in hospital, potassium bromide was administered in gradually increasing doses with, so far, very pleasing results. The patient has had no further fits of major or minor epilepsy, though it is now just seven weeks since this line of treatment was commenced. The paroxysms of tachycardia have reduced in frequency, more so in duration and severity. For the last two weeks she has had but three paroxysms, each of which was mild and lasted only five minutes.

It is not my intention to enter into the clinical details or the supposed etiology of the interesting symptom, tachycardia. Dr. Finny has dealt with the subject very fully, has recorded three instructive cases, and has compiled a careful bibliography, to be found in Vol. XVII. of our Transactions. Suffice it to say now that tachycardia in some instances is merely a symptom which may be due to diverse causes. Among these are organic disease of the heart or vessels, exophthalmic goitre, toxic states, and fevers. Such tachycardia has been styled "symptomatic" in contradistinction to the variety in which the rapid action of the heart, usual in paroxysms, appears to be the sole manifestation of any morbid state. This variety has been called "essential," its etiology is still enveloped in a cloud of mystery. Trousseau suggested the phrase "partial epilepsy," and Talamon "cardiac epilepsy" in this connection. The idea, therefore, that some cases of essential paroxysmal tachycardia may be fundamentally similar from a pathological standpoint to epilepsy, is not new. Yet, in the literature of the subject I can find no record of a case (though it is highly probable that such exists) in which paroxysmal tachycardia and epilepsy were as intimately associated as in that above related. The association may be thus summarised:—

1. The patient inherited predisposition to epilepsy, three of her mother's first cousins, each of separate parentage, suffering from it.

2. The tachycardia commencing in early life, its sudden paroxysmal nature, its mysterious appearance, disappearance, and reappearance; its tendency to become more frequent and severe, are all suggestive of functional epilepsy.

3. The patient's vacant look in a paroxysm, the impairment of memory, occasionally amounting to unconsciousness, indicate a mild degree of the psychical disturbances of epilepsy.

4. The occurrence of polyuria after a paroxysm of the heart as after epilepsy. (Verified in hospital.)

5. Minor epilepsy showing itself as well as the tachycardia, both occurring frequently, but without apparent order or sequence.

6. The subsequent appearance of major epilepsy in the same patient.

7. The decided improvement (if only for the time being) of the paroxysmal tachycardia on the administration of potassium bromide.

8. Perturbation of the heart's action has been observed as an aura in epilepsy.

In fact, it appeared in this particular case, that epileptic "nerve storms" were more prone to sweep in the direction of the heart than in that of the voluntary muscles, but whatever their direction might be, they temporarily devastated, to some degree, the higher physical centres. This theory is not suggested as a serious elucidation of the pathology of the case; at best, it is only somewhat less hypothetical than the explanation which would have been proffered in the Middle Ages, namely, that at times the demon of epilepsy entered the girl's heart. My experience, however, will prompt me to give potassium bromide a fair trial in the next case of paroxysmal tachycardia that falls to my lot, on the supposition that it may possibly in some instances be a rare manifestation of epilepsy.

THE PRESENT STATE OF THE LEPROSY QUESTION IN INDIA AND CEYLON. *(a)*

By JONATHAN HUTCHINSON, F.R.S., F.R.C.S., &c.,

Emeritus Professor of Surgery at the London Hospital.

We are here in the interest of a tenth of a million of our fellow-subjects who are, at the present time, in our great Indian Empire, sufferers from the disease known as leprosy. They are, for the most part, poor and ignorant, and quite incapable of devising measures to prevent the perpetuation of this curse. It is for educated Englishmen, many of them trained investigators, to bring their knowledge and reasoning powers to bear upon the facts for their benefit. It is at least thirty years since I first planned the tour of investigation which I now hope to accomplish. In the interval I have read everything which has come to hand on the subject, and have taken the evidence of a large number of medical men, missionaries, and others who have resided in India. Through the whole of this period I have held firmly the conviction, which has strengthened as years have advanced, that leprosy is in the main a food disease, that it spreads only to a very small extent by anything of the nature of personal contagion, and that the one article of food which is to be suspected is badly-cured fish, eaten without its being sufficiently cooked. In all ages, and in almost every country where leprosy has prevailed, the popular belief has been that the eating of fish is in some way connected with it. References to this belief are numerous in the writings of old authors, and in a large majority of modern local reports there occurs some allusion to the fish-eating habits of the community. The way in which the disease has waned and ultimately almost ceased in Europe with advancing civilisation is also in harmony with this belief. It advanced in inland districts of Europe with the advent of Christianity and the observance of fish fasts, and it disappeared when Protestantism threw these fasts into disuse. Other influences also took their share, the development of agriculture and the increased production of other kinds of food being among the chief. Norway and Iceland have always been conspicuous for the prevalence of the disease. The former has from time immemorial had the largest fishing trade in the world, and of the latter an old geographer wrote that it ought to be named "stock fish." In both these places fish is still very largely consumed, and in both the prevalence of leprosy, in proportion to population, exceeds that of India. It will probably be very near the truth to say that over the whole world at the present day the prevalence of leprosy is in ratio with the use of cured fish as an article of diet. A suggestion has recently been made in reference to the precise mode in which leprosy might be communicated from one person to another, which, I think, goes far not only to reconcile the two schools of contagionists and non-contagionists, but to explain away, for the most part, all the facts which have been supposed to imply hereditary transmission. It is that the only way in which the living bacillus can be received into the system is by the stomach, and that practically such communication takes place only when food is eaten which has been contaminated by a leper's hands. To this mode of communication the term "commensal" may suitably be applied. It will probably astonish many of you to learn that, after all, leprosy is not very prevalent on the mainland of India. The popular belief is that the disease is scarcely known in South Africa, and that it overruns India as a special curse. It is, as a matter of fact, in ratio with the population, as common in one as in the other, and in neither does it exceed that which, in spite of the boasted results of segregation, still obtains in Norway. In all these three places its average prevalence is something less than 5 per 10,000. In Ceylon it does not reach 2 per 10,000; but in some of the smaller islands off the coast of India—Minicoy, for instance—where fish is eaten by the labouring population three times a day—its prevalence reaches the enormous ratio of 100 or 150 per 10,000. In some countries, as in South Africa, lepers carefully conceal themselves, whilst in others, as in India, seeking charity they parade their miseries. Among the more important inquiries which I propose to keep in view in India is the inquiry, from those qualified to judge, as to whether the statements made by certain Hindus and Brahmins that they have never eaten fish are trustworthy.

(a) Abstract of lecture delivered at the Polyclinic in connection with the Prince of Wales's Leprosy Fund.

Clinical Records.

THE SEAMEN'S HOSPITAL, ROYAL ALBERT DOCK.

A case of strangulated inguinal hernia, in which "reduction en masse" was caused by the employment of taxis. (*a*)

By Lawrie McGavin, F.R.C.S.Eng.

The patient, a man, æt. 52, a dock labourer by trade, was admitted to the Seamen's Hospital, Royal Albert Dock, on September 20th, 1902, with the following history. For nine years he had suffered from a right inguinal hernia which had always been easily reducible, no signs of strangulation having ever been present. On the night of September 14th, however, the rupture suddenly came down and he was unable to get it back. He immediately called in a medical man who made several ineffectual attempts at reduction by the use of taxis. On the last attempt the mass partially disappeared, and the patient at once experienced great pain, and almost immediately commenced to vomit. On the following day the vomit became stercoraceous and continued so till admission, nothing further apparently being done for him.

On admission the patient was evidently *in extremis*, and appeared to be suffering from general peritonitis. His temperature was subnormal, and his pulse 115 and thready and dicrotic. The abdomen was very distended, and there was some tenderness, especially over the right iliac fossa, but no mass could be felt there. In the right side of the scrotum a soft mass was noticed, which, in view of the abdominal condition suggested collapse of the bowel from perforation, with possibly some omentum still strangulated in the sac. Neither flatus nor motion had been passed for six days; the tongue was dry and brown, the breath extremely foul, and the abdominal type of face well marked. In the hope of being able to do something for what I thought might be a partial reduction of a "hernia en bissac," with rupture of the bowel at the neck of the sac, I had the patient removed to the theatre. Gas and ether were administered, but before three breaths of pure ether had been taken he suddenly ceased to breathe. Artificial respiration was therefore resorted to, but he almost at once vomited a quantity of fæculent matter and died.

At the autopsy the following condition was disclosed: The right side of the scrotum contained a flaccid vaginal hydrocele of moderate dimensions, above which the cord was slightly thickened; there was neither bruising nor ecchymosis of the scrotal contents.

On opening the abdomen some foul fluid escaped. The bowels were distended, and on tracing the small intestine downwards it led to a point in the ilio-inguinal region, below and rather internal to the tip of the cæcum, where it was found to enter what appeared to be the internal abdominal ring, whose margins were much thickened as from old-standing irritation, and whose aperture measured about an inch in diameter. This was situated over a bulging mass in the iliac fossa, and lay behind and external to the cæcum. On dividing the peritoneum over this mass a sac was reached, which on being opened appeared to be the original sac of the hernia. It contained a portion of the ileum (which measured about ten inches in length) in a condition of extreme congestion, almost gangrenous at the point of constriction and its mesentery. The site of the strangulation was about a foot above the ileo-cæcal valve.

General peritonitis was present, but no actual perforation could be found. The heart was firmly contracted in systole, although the larynx was full of fæcal vomit.

I have thought this case worthy of publication as much on account of its moral lesson as of its clinical interest, for it serves to emphasise what has been so repeatedly pointed out by many authorities, that the attempt to reduce a strangulation of the intestine by taxis is unwise, and that when persisted in repeatedly, such treatment is quite unjustifiable.

It is, I believe, unwise to attempt reduction by taxis

(*a*) Read before the Clinical Society of London, November 28th, 1902.

at all, unless the congestion of the bowel be first, to some extent, relieved by the application of ice (in cases where it is thought that the vitality of the bowel will not be interfered with by such treatment), and in cases where the vomit is fæculent it is certainly so.

It is under any circumstances, a step taken in the dark, for unless we can answer certain questions, we are obviously exposing the patient to risks of which he knows nothing, and from which we, as surgeons, ought rather to safeguard him. First, is the bowel ulcerated? Secondly, is it adherent to the neck of the sac? Thirdly, can we be certain that there are no adhesions across the neck of the sac, over which we may possibly reduce the contents? and lastly, are we dealing with a "hernia en bissac?" Again an element of uncertainty lies in the structural condition of the bowel in question, for just as the skin of one patient differs in texture from that of another, so in one patient the bowels may be thin and semitranslucent, while in another they may be thick and opaque. It is clear that taxis will damage the first more easily than the second under similar conditions.

In view of the fact that disasters have happened and will happen again, it is, I think, time to abandon taxis as an empirical measure, unworthy of the name of sound surgery.

Admitting that taxis were a justifiable measure, how long may it be persisted in, and how much force may be exerted? Here are two questions which are obviously without sense, for each depends on the condition of the bowel, which is invisible to the eye, and the second to a great extent on the lightness of touch and the muscular power of the individual surgeon, both of them inestimable qualities, and varying considerably in most of us.

Glancing for a moment at the standard text-books on the subject, we find an attempt made in each to limit the duration of taxis; thus, in one case, ten minutes; in another five, in another "a few minutes," and in another three to five minutes are given as the time limit, all of them advising only "a moderate degree of force." Thus the advice given is of a very indefinite order, and leaves much to be desired in the question of standardisation. The most definite opinion of all on the subject is to be found in Messrs. Watson Cheyne and Burghard's recent work, in which the authors frankly condemn the practice in view of the slight risks of the operation of kelotomy.

Reviewing the dangers of taxis, one cannot help wondering how any surgeon can be willing to face the responsibility of them, for all are serious, and in many the condition of the patient is rendered well-nigh hopeless; in all the mortality is very high.

Thus "Reduction *en masse*" has a mortality of 57 per cent. for all herniæ (inguinal 50 per cent; femoral. 73·6 per cent. (*a*)

Resection of small intestine for gangrene, 50 per cent. (*b*)

Suppurative peritonitis (in cases operated on), 60 per cent. (*c*)

There must be considered also the possibility of asphyxia from fæcal vomiting if the case eventually comes to operation, as in the case I have reported; of septic pneumonia, and even (in the highly improbable event of spontaneous cure) of the occurrence of an intractable fæcal fistula. Against these heavy odds must be placed the post-operative mortality of kelotomy, which if performed within twenty-four hours stands at 10 per cent. to 12 per cent., but if over three days from the time of strangulation at 50 per cent. (*d*)

While I, personally, do not recognise the position of taxis under any circumstances, as a sound surgical measure for the relief of strangulated herniæ I am fully aware that there are many surgeons who still admit its utility. I would, therefore, in deference to these authorities, suggest the following conditions as being those in which such treatment is absolutely contra-indicated, and it will be seen that the margin in which cases suitable for treatment by taxis may be found, is a very narrow one.

(1) All femoral cases, for those are usually found in women whose intestines are thin, the bowel commonly tightly constricted, and lying on the knife-edge of Gimbernat's ligament in a canal whose peculiar shape renders reduction somewhat difficult at all times.

(2) In all inguinal and umbilical cases when (a) the strangulation is more than twelve hours old; (b) the hernia has long been irreducible; (c) the vomit is fæculent in the least degree; (d) the hernia is a large scrotal one of old standing with a tight ring, such hernia, as Rowlands points out, being those which are most prone "to reduction *en masse*"; (e) any sign of inflammation is present; (f) pain is a marked symptom; (g) the attempt has already failed.

"Reduction *en masse*" is a comparatively rare occurrence, and Rowlands,(*a*) in his recent investigations on 100 cases, points out that at Guy's Hospital only fifteen cases have been recorded in the last forty years; the subperitoneal reduction into the iliac fossa being the usual variety.

In my own case, the chief points of interest are, I think, the large size of the mass reduced, the entire absence of damage to the contents of the scrotum, the question raised by the death of the patient, as to the advisability of washing out the stomach prior to operation, and that of the best method of dealing with these cases.

With regard to lavage, Treves (*b*) has recommended this plan, and the soundness of it must be obvious to all surgeons, for in urgent cases, the immediate danger of suffocation under the anæsthetic is considerable, and in the post-operative treatment the risk of septic pneumonia is reduced, as is also the danger of absorption of fæcal material from the stomach.

A point of importance is, I think, that if it is done at all it should be done previous to the administration of the anæsthetic, in view of the possible embarrassment to an already feeble respiration.

In the present instance I did not consider it wise to attempt lavage owing to the extreme urgency of the case. As to the method of operating in these cases, the idea of performing a laparotomy before investigating the state of the bowel at the seat of constriction through the inguinal canal seems to me dangerous, from the possibility of rupturing it at a weak spot in the attempt to withdraw it from the sac. That such operations are successful is evident from the fact that Erichsen (*c*) mentions three cases, two by Thorburn and one by Barker, which resulted in cure; but when the diagnosis is in doubt, or, as in the case recorded by Rowlands in his paper (*a*), where perforation into the sac has actually taken place, the performance o laparotomy must be an extremely dangerous practice.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, NOVEMBER 28TH, 1902.

MR. HOWARD MARSH, F.R.C.S., in the Chair.

MR. A. W. MAYO ROBSON (Leeds) read a paper

ON RUPTURED CRUCIAL LIGAMENTS AND THEIR REPAIR BY OPERATION.

The patient was a miner, æt. 41, admitted to the Leeds General Infirmary, November, 1895, for lameness, the result of an accident nine months before, when he was almost buried by a fall of earth and sustained numerous injuries, besides the one to the joint in question. When admitted to the infirmary, the right knee was swollen but free from tenderness on manipulation. When the muscles were pressed the bones were in good position, but as soon as the muscles were relaxed the

tibia fell backward until stopped by the ligamentum patellæ and on manipulation the head of the tibia could be brought forward in front of the femur, there being also free lateral movement of the head of the tibia on the femur and some fluid in the joint. It was manifest that not only were all the ligaments relaxed, but that the crucial ligaments had been ruptured. On November 21st, 1895, the joint was opened by a semilunar incision carried across the front and dividing the ligamentum patellæ. The synovial membrane was found inflamed and there was an excess of fluid in the joint. Both crucial ligaments were found completely ruptured, having been torn from their upper attachments, the ends being in a shredy condition. They were stitched in position by means of catgut ligatures, the anterior being stitched to the synovial membrane and tissues on the inner side of the external condyle, and the posterior, which was too short and was split in order to lengthen it, was fixed by sutures to the synovial membrane and cartilage on the outer side of the inner condyle. The wound was then stitched up by means of buried catgut sutures, and was closed superficially by interrupted silk-worm gut sutures. The result was very successful, complete restoration of the normal movements of the joint having occurred.

The stitches were removed on December 4th, and on the 14th plaster of Paris was applied, and he was allowed to get about on a Thomas's splint and to go home. The plaster was removed in a month, after which movement gradually returned under massage. When seen on October 24th, 1901, the patient was walking without a limp and could run. He said that his leg was perfectly strong, and that he could work eight hours a day at his old employment of getting coal, and that he had never been off work a day on account of his knee since the year of his accident The joint could be extended to the straight line and flexed just beyond the right angle, there being no abnormal lateral or antero-posterior mobility whatever. The author had not discovered any other case in which these ligaments had been re paired, which he trusted was a sufficient excuse for his recording a single case.

The President commented on the fact that such strong non vascular structures could be ruptured in this way. He questioned the advantage of opening the joint when actively inflamed if that course could be avoided, and he related an illustrative case. He also referred to the case of a lad whose knee after the injury was in a flail-like condition, but six months later the joint was found to be fairly serviceable.

Mr. W. G. **Spencer** doubted whether such strong ligaments could be quite ruptured, and whether, if that were the case, the attachment by scar tissue would be sufficiently strong. In many cases, moreover, a plate of bone was torn away together with the ligament.

Mr. **Mayo Robson**, in reply, concurred in the general view not to operate upon joints in a state of acute inflammation. In his own case the limb was absolutely useless nine months after the accident, and the only alternative would have been amputation.

Lieutenant-Colonel W. K. **Hatch**, I.M.S., read a paper on

HEPATIC ABSCESS,

of which he said he had exceptional opportunities of treating. Altogether, in the Sir Jamsetjee Hospital and in private practice, he had seen upwards of 1,000 cases of this disease. He pointed out that the disease was common enough among natives, and, though alcohol was a factor, the majority had suffered from dysentery. In discussing the diagnosis, he insisted on the strong hepatic odour which emanated from the patient. Sometimes percussion gave a resonant note over the abscess, due, no doubt, to the passage of gas from the neighbouring colon. If situated near the middle of the liver, near the ensiform cartilage, pulsation might be propagated from the aorta, thus complicating the diagnosis. He wished particularly to call attention to the fact that aspiration was attended with a certain amount of danger, and ought, in fact, only to be employed when the diagnosis had been established, and it only remained to determine the precise locality of the abscess. The danger lay either in puncturing an enlarged and highly congested liver or in wounding a large hepatic vessel. Dangerous and even fatal hæmorrhage might thus be caused, in some instances from puncture of the vena cava. His practice was to open the abdomen by a two-inch incision, exposing the liver, which enabled him to introduce the canula with greater safety. In a case to which he referred, hæmorrhage followed which ceased on manual pressure, but the patient died. As regards surgical treatment he thought incision was unquestionably the proper treatment, and the earlier the better, though it might be well first, in large abscesses, to draw off part of the pus, making the incision a day or two later, thus lessening the chance of its becoming septic. He preferred to open between the ribs rather than below them. Even in cases where the abscess contents were being expectorated he preferred to incise. He deprecated removal of ribs as quite unnecessary. He never irrigated the abscess cavity unless it became septic. The mortality in hospital practice was high—in 1897 as high as 97 per cent.

The **President** asked whether the author had made use of the method of diagnosis by leucocytosis. He commented on the fact that the author apparently did not attach much importance to cutting into the abscess through the peritoneum, a procedure which was usually held to entail considerable risk. He himself, under such circumstances, preferred to expose the abscess and pack gauze around the presenting part, so that in the course of a day or two adhesions might form and so shut off the peritoneal cavity, and he mentioned a case in which he had adopted this procedure with success.

Mr. **Bowlby**, in some remarks on the subject of attacking these abscesses through the pleura recalled that it had been alleged that as the pus was sterile there could be no objection to allowing it to escape through the pleura, but he thought it was generally held to be desirable to shut off the pleural cavity. Even if the pus were originally sterile it probably did not remain so.

Mr. **Mayo Robson** (Leeds) said the author had done good service if only by calling attention to the risks of indiscriminate blind exploration. This was still very widely practised. The exploration of suspected distended gall-bladder, he trusted, was a thing of the past. It was much safer in abscess of the liver to open the abdomen when they could see what they were doing, and could the more easily arrest bleeding if required. He did not feel sure that it was always desirable to perform the operation *en deux temps*, because that prevented their exploring the region in order to find out whether other abscesses were present. When exploring the liver he preferred to pack the wound with sponges, and if pus were found it could be evacuated before making a free incision He therefore either made a free incision into the peritoneal cavity or else excised a rib or two in which case he certainly preferred to stitch the two pleural surfaces together to prevent the pus entering the pleural cavity.

Dr. **Longhurst** expressed surprise at learning that abscess of the liver was so common among the natives of India and asked how the author explained this circumstance?

Dr. **Busch** said that during the last ten months he had opened four abscesses through the pleura, in three he had made an exploratory aspiration, and immediately afterwards he had excised a few ribs, stitching the pleura to the diaphragm. Two recovered without any trouble, the third did well for a month, but then became maniacal and died. In none of these three cases was there any trouble with the pleura. In the fourth case there had been a great many aspirations, and no doubt the needle had been pushed through the pleural cavity, that patient developed an empyema from which he died. He pointed out that aspiration on suspicion of abscess of the liver might be attended by serious consequences.

Mr. **Stephen Paget** asked what was the risk if they opened the abscess freely? On two occasions he had found it useful to pass a silver director down towards the syringe, and then with a probe-pointed gorget, pushing aside the liver tissue, thus minimising the risk of wounding a vein.

Lieut.-Colonel **Hatch**, in reply, said he had not resorted to leucocytosis for diagnostic purposes. He thought there was a positive advantage in not pushing the surface of the liver away from the abdominal parietes. He had never met with any bad results from the passage of the pus into the peritoneum, nor had the pathologist to the hospital recorded any evidence of peritonitis from that cause. Beyond some dyspnœa he had not seen any danger from opening through the pleura, and he did not specially suture the pleura to the surface of the thoracic wall. His object was to show that great care should be used in exploring, particularly in the cases in which there was no abscess at all, since it was in those cases that it did most harm. In view of the extreme disagreeableness of expectorating the pus of a hepatic abscess he would not hesitate to operate in such cases.

Mr. **Lawrie McGavin** read notes of a case of "Strangulated Hernia with *Reduction en masse*," which will be found on page 599.

Mr. E. G. L. **Goffe** suggested the use of a local anæsthetic in such cases, such as eucaine, &c. He had witnessed very good results therefrom.

Mr. W. G. **Spencer** observed that taxis was largely resorted to, and, perhaps, one only heard of the successful cases.

Mr. **Bowlby** observed that many cases of *reduction en masse* were cases in which the taxis had been applied by the patient or his friends. He had never seen a case in hospital in which it had followed taxis applied there. It was quite possible that the measure of force applied by people outside the hospital may have been beyond anything that was reasonable and right. He opined that it would lead to considerable loss of life if taxis were quite abandoned. Even if the mortality from operation were only 10 per cent., as alleged, the mortality of taxis applied within twenty-four hours would not be nearly as much, for in the majority of cases it was reduced with a minimum of force, and a reasonable amount of force was probably quite safe.

Mr. H. **Symonds** (Oxford) said that as the surgeon of a county hospital for twenty years he had always forbidden taxis to be applied, preferring to operate forthwith. The damage was done in cases in which there was no omentum in the sac, in which event a comparatively small amount of pressure might do great harm.

Mr. **Openshaw** agreed that in femoral hernia, hernia with a tight neck, cases in which there was marked collapse and in which the symptoms had lasted some time, taxis was inadvisable. Nevertheless, he himself applied taxis in some cases and not without success. He had not seen more than one or two cases in which taxis had done harm.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

Meeting held Friday, November 21st, 1902.

President, Dr. A. V. **Macan**, in the Chair.

Dr. **Finny** read the notes of a remarkable case of

ERYTHEMA MARGINATUM PERSTANS

in a lad, æt. 21, who had been under his care in Sir Patrick Dun's Hospital for the last five weeks. The case presented two prominent features (1), of having lasted off and on for over three years, and (2), of the curious marginate lines the disease assumed. Hence he described it as Erythema Marginatum Perstans. The eruption, for which no cause could be assigned, occurred suddenly, with a sensation of malaise, and came out first on the thighs, knees, and trunk; lately spreading more on the arms to the wrists, and on the legs to the dorsum of the feet. It has spared the face, scalp, and upper part of the neck. When appearing it is itching and tingling somewhat like a hive, but the itching is slight as a rule. The eruption presents a polymorphism found in erythema multiforme—papules, circles, segments, gyrated patches, and long lines, erythema marginatum. The lines are chiefly found on the thighs and near the axilla on the thorax and upper arm, and present curious devices. The eruption is pinkish-red, red, or reddish-brown. Its mode of growth can be readily studied, commencing as a papule the size of a small pea, smooth, non-vesicular; it rapidly spreads peripherally, and in three to four days forms a circle, the centre being of the normal skin hue, while the encircling raised margin widens out. Should it meet another similar circle, the meeting arcs break down and a gyrate irregular body is the result. Again, one side of the circle may disappear, and the remaining coloured rim may end in long, wavy, or hooked lines, the terminals being as sharply raised above the skin as the rest of the line. In a very few instances a little vesiculation was detected, due to rubbing or scratching. There were no examples found of "erythema iris" or "erythema nodosum." The diagnosis lay between erythema multiforme and eczema dermatitis herpetiformis, urticaria, and the gyrate forms of psoriasis. The distinguishing features were discussed, and reference was then made to the rarity of the disease, as judged by the reticence of or slight passing mention made in, the standard works on diseases of the skin (including Stelwagon's, vol. 1902) on this particular variety, and with the exception of three instances, which showed a very limited distribution of erythema gyratum of a lasting duration, there were no references to or exhibits of it in the volumes of the *American Journal of Skin Diseases* or in the records of the Dermatological Society of Great Britain. There was one unusual symptom present, namely, enlargement of the glands in the groin and axilla. No special treatment seemed to do good, though the improvement which has followed a course of thyroid extract may justify its use as a therapeutic agent of some value.

Dr. **Walter Smith** said he had never seen a parallel case, but showed an illustration, published by Dr. Fox in the International Library of Rare Skin Diseases, which was almost a reproduction of Dr. Finny's illustration. His own inclination was to refer the case to erythema multiforme, but the boundaries of the erythema group were very badly defined. Accounts published by experts of diseases classed under erythema multiforme led to great confusion. There were two features to be noted in the case (1), the serpentine, gyrate outline; and (2) its persistency and rebelliousness to treatment. He referred to a case which he had had in the Adelaide Hospital, in which the gyrate outline was very well shown: several of the rings of erythema were tipped with vesicles and conjoined with vesication; no one hesitated to class it as erythema multiforme. Referring to its persistency, Dr. Smith quoted a pair of cases of the affection which had occurred in a brother and sister, in which the eruption persisted for a considerable time; the cases were evidently similar, the eruption beginning with papules, then going on to patches, circular, annular, and gyrate.

Dr. **Wallace Beatty** said he had never met a case like Dr. Finny's, and referred to the figured eruption which is seen in cases of psoriasis, a figuration which resembled that seen in the case they were discussing.

Dr. **Doyle** described a somewhat similar case.

Dr. **Finny**, in the course of his reply, said he was inclined to try large doses of quinine.

Dr. R. **Travers Smith** read a paper on a case of

PAROXYSMAL TACHYCARDIA ASSOCIATED WITH EPILEPSY,

which will be found on page 597.

Dr. **Finny** thought with Dr. Smith that the tachycardia and the epilepsy were allied in this case.

A CASE OF LYMPHADENOMA WITH RECURRENT PYREXIA.

Drs. **Bewley** and **Scott** described the above case. A gentleman, æt. 35, suffered from a mild attack of typhoid fever with two relapses, which lasted from October, 1900, till the end of January, 1901. In March of the same year he again developed a high temperature. The fever ran a severe course, being accompanied by delirium and much weakness. For it no cause could be discovered; all the viscera, the blood, urine, &c., were normal on examination. The fever lasted six weeks and ended by crisis. A third attack of high fever lasted from the middle of May till the end of June. A fourth attack commenced early in November and lasted three weeks, when the patient died of heart failure. The first attack was proved by Widal's reaction to be enteric; but in the other three attacks there was no abnormality to be found by any mode of examination, and no diagnosis could be made. The blood count in November, 1901, was: Red corpuscles, 3,725,000; white corpuscles, 6,200; hæmoglobin, 37 per cent. At the autopsy a mass was found in the mediastinum lying above the heart, about four by five inches in size, consisting apparently of enlarged lymph glands fused together. There were a few secondary nodules in the lungs and abdominal organs. The spleen was enlarged, and contained some firm pale-coloured masses. These tumours were composed of fibrous tissue, with a few lymph cells lying between the bundles. No microbes could be detected anywhere. In a considerable number of cases of lymphadenoma recurrent pyrexia has been observed. It has by some observers been attributed to the presence of micro-organisms, while others have thought that some chemical toxin formed by the lymphomatous masses was the cause of the pyrexia.

LIVERPOOL MEDICAL INSTITUTION.

Meeting held Thursday, November 20th, 1902.

The President, **Rushton Parker**, Esq., B.S., F.R.C.S., in the chair.

Mr. **Bickerton** showed a case of Symmetrical Corneal Opacities, which was commented upon by Drs. **Grossmann** and **Barendt**.

Mr. R. W. **Murray** related the case of a lad, æt. 16, upon whom he had operated in April last, for what was thought at the time to be subacute appendicitis. The operation revealed a strictly limited hyperplasia of the cæcum and adjacent portions of the ileum, with a small abscess, probably glandular, behind the cæcum. The abscess was drained, and ten days later a fæcal fistula formed. In July, as the general health was failing, Mr. Murray opened the abdomen away from the affected area, and short-circuited the intestine, joining ileum to transverse colon. end to end, by simple suture. The fæcal fistula closed, but the patient's general condition was still far from satisfactory. In this case, one probably of tuberculous hyperplasia of the cæcum and ileum, Mr. Murray thought excision of the diseased portion of the intestines impracticable.

Dr. W. **Blair Bell** gave the early history of the case, and could not agree with Mr. Murray as to the nature of the condition. In Dr. Bell's opinion it was not tubercular.

The President, Mr. Monsarrat, and G. G. Hamilton spoke, and Mr. **Murray** replied.

Dr. **John Hay** showed a man, æt. 38, suffering from the tonic form of progressive muscular atrophy, which had commenced four months after an attack of lobar pneumonia.

Dr. T. R. **Bradshaw** remarked that the case was the type commonly known as amyotrophic sclerosis, more often seen in women, and running a much more rapid course than the purely atrophic cases.

Dr. **Macalister** and Dr. **Bradshaw** read a paper on the

INFLUENCE OF SMALL DOSES OF SALICYLIC ACID ON DIGESTION AND NUTRITION, WITH SPECIAL REFERENCE TO ITS EMPLOYMENT AS A PRESERVATIVE IN FOOD.

Evidence had been given in various courts and in Parliamentary Committees which was of the vaguest description, depending less upon actual observations upon the results of taking salicylic acid itself than upon the results of taking other antiseptics. It had been argued that salicylic acid was ten times stronger than carbolic acid, with the view to proving that it was more injurious, which was obviously absurd. They considered that the recommendation that not more than one grain per pint of the acid might be used was made without any foundation in evidence that the quantity was generally quite inadequate as a preservative, and that the recommendation was unsatisfactory because it made no distinction between the various substances it was intended to preserve, and the various quantities in which they were likely to be consumed. The writers were strongly of opinion that the nature and amount of preservative employed ought to be stated on the label. They had found that it was contended that salicylic acid was injurious for three principal reasons:—1. That it was antiseptic and anti-fermentative and therefore liable to interfere with the digestive processes by destroying the digestive ferments. 2. That after absorption it was apt to injure the general health and to interfere with nutrition. 3. That it was an irritant and therefore apt to injure the mucous membranes of the stomach and intestinal canal. They had reason to believe that many who were opposed to the use of salicylic acid on the first ground did not distinguish between true digestion and decomposition. The writers had made numerous experiments on artificial digestion and they found that the presence of salicylic acid even in saturated solution had about the same effect in retarding peptic digestion as the same proportion of kitchen salt. In pancreatic digestion of starch it seemed to have no retarding influence at all after neutralisation. As regards the second objection, one of them had taken 5 grs. of salicylic acid daily for a month without any ill effect on the health; they had given it to children in fruit juice preserved with it, and they had watched its effects on other persons, and they found that it exerted no recognisable bad effect whatever. As regards the objection that salicylic acid was an irritant to the mucous membrane, they denied that it could be so in any such degree of concentration as it was possible to obtain it, either in food or in the stomach contents. They maintained that salicylic acid as an antiseptic was of the greatest value to the poorer classes in towns by enabling them to obtain luxuries such as non-alcoholic wines free from the risk of decomposition, and at a moderate cost, and thus enabled the public to obtain cheap, wholesome, and agreeable beverages, free from the risk of moral and physical evil which attended the use of alcohol drinks. They challenged the opponents to bring forward a single instance in which it could be shown that bodily harm had resulted from salicylic acid employed as a preservative, and they denied that it was possible for anyone to be injured by it in the proportion in which it existed in any of the preserved articles which had been brought to their notice.

Mr. F. T. **Paul** had supported the Medical Officer of Health in his endeavour to check the excessive use of salicylic acid as a food preservative on the grounds that (1) chemical preservatives were undesirable, (2) salicylic acid was a poison, (3) it was unnecessary to preserve the articles in which it was used. The first was an opinion shared by most medical men. The second point had been sufficiently proved at the time salicylic acid was largely given for acute rheumatism, and he referred members to a paper he read before the Society in 1876. As regards the third, it was admitted by the manufacturers of the fruit juices that they only used large quantities of salicylic acid in order to prevent alcoholic fermentation, and the consequent presence of minute chemical traces of alcohol repugnant to the teetotaller; otherwise one or two grains to the pint would be sufficient. The other food substance for which salicylic acid was so largely used was bottled fruit, the flavour of which it completely destroyed. Heat sterilisation in this case was alone necessary, as he had proved by extensive experiments. He agreed with other speakers that so small a quantity as 1 or 2 grs. to the pint was probably harmless, and need not be objected to if stated on the label.

Mr. **Bickerton** could not understand speakers denouncing salicylic acid as a "poison." He and his family had during the summer months drunk the special preparation around which controversy had raged—"Patterson's Raspberry Fruit Juice"—with no appreciable effect one way or the other. He understood it had contained 19 grs. to the pint; a little of the juice only was used at a time in a tumblerful of water or soda water. The proof of the pudding was in the eating. Salicylic acid in the strength above mentioned had neither done harm to himself nor his children, nor had he seen any ill effect produced on patients to whom he had prescribed it. As to the reported injurious effects on the mucous membrane of the stomach, he doubted it. It was quite possible the symptoms of irritation were due, not to the drug itself, but to impurities in its manufacture. He had applied a saturated solution of salicylic acid to his own eye, and it had no effect whatever, not even causing smarting or watering.

Professor Moore, Drs. Barr, Grünbaum, Buchanan, and Mr. Damer Harrisson spoke, and Drs. **Macalister** and **Bradshaw** replied.

Mr. G. G. **Hamilton** described a method for removing foreign bodies from the œsophagus. The main point lay in going in search of the coin whilst the X-rays were being used. Thus accurate adjustment of coin and coin-catcher was possible.

GENERAL MEDICAL COUNCIL.

SEVENTY-FIFTH SESSION, NOVEMBER, 1902.

Sir W. Turner, President, in the Chair.

FIRST DAY.—Tuesday, November 25th.

Presidential Address.

Sir William Turner stated that no change had occurred in the *personnel* of the Council since the last meeting. By the passing, on July 31st, of the Act to secure the better training of midwives and to regulate their practice, statutory recognition had been given in England and Wales to an order of obstetric practitioners who had not hitherto had a legal position and title. After drawing attention to certain of the provisions of the Act, he said that he understood that the Central Midwives Board was now fully constituted. The General Medical Council was to take no part in the formation and administration of that Board, and its duty under the Act was restricted to that of making representations with respect to the rules framed by the Central Midwives' Board before those rules were approved by the Privy Council. So far as the General Council was concerned, the midwives' question, which for so many years had occupied much of their time and attention, need no longer find a place in their programme of business. Under the Midwives Act, and in association with the legal recognition of midwives, from which Scotland and Ireland were expressly excluded by statute, Parliament had delegated to the English Branch Council special powers to act for a specific purpose, as if it were the General Council. A new departure had therefore been made in medical legislation, and an independence of action had been granted to the English branch such as had not been conferred on the other branches. Each of the constituent provinces of the Dominion of Canada had, as regarded regulations affecting medical practice, been independent of its neighbours, so that a qualification granted in one province had not empowered the person holding it to practise in the other provinces. During the last few years leading members of the profession in Canada had considered the advisability of doing away with such restrictions, and of obtaining a Medical Act applicable to the whole Dominion, and framed generally on lines similar to the Medical Act of 1858, which granted equal rights to practise in the three divisions of the United Kingdom to holders of qualifications obtained in any one of them. On May 15th last, by the Canada Medical Act, 1902, a Medical Council of Canada was constituted. The purposes of this council were to establish a qualification such that the holders thereof should be empowered to practise in all the provinces of Canada; to establish and maintain a board to examine and grant certificates of qualification; to establish a Canadian register of medical practitioners: and to determine and fix the conditions and qualifications necessary for registration. But the Act also contained sections which had a special interest to the Medical Council of the United Kingdom. Under section 4 (e) the Canadian Medical Council was empowered to establish such a status of the medical practitioners in Canada as should ensure recognition thereof in the United Kingdom, and enable Canadian practitioners to acquire the right to registration unde the Medical Acts of the Imperial Parliament. The Canadian Medical Council might make regulations so that licences granted by any British, Canadian, Colonial, or foreign licensing body or authority should be recognised and authorised to arrange for a scheme of reciprocity as to registration, and the terms and conditions upon which medical practitioners duly registered or licensed under the Medical Acts of the United Kingdom should be entitled to registration in Canada. The regulations under this section of the Canadian Medical Act did not take effect until they had been approved by the Governor in Council. When these provisions of the Canadian Act had been complied with, Part II. of the Medical Act of 1886 would become applicable to Canada, should it appear that Canada afforded to the registered medical practitioners of the United Kingdom such privileges of practising as might seem just. Canada would thus be placed on the same footing as India, Malta, and the sister colonies of New Zealand and Australia, and another step would be taken in the consolidation of the British Empire. As a further indication of the activity displayed in the Colonies in the establishment of medical boards, and in the recognition of the right to practise by those whose names were on the *Medical Register* of the United Kingdom, he mentioned that the administrator of the Orange River Colony had issued a proclamation similar in its terms to that issued early in the year for the Transvaal. The inspection of the final examinations of the English Universities, and of the medical and surgical corporations in Ireland, had been in progress during the year. Only Cambridge University now remained to be visited. The Council had received from the Royal Colleges in London information supplied by the examining board in response to questions put by the Council as to the courses of study in chemistry, physics, and biology at teaching institutions recognised by the Royal College, but not approved by the Council. The executive committee had directed that the answers given by these institutions should be printed and circulated for the information of the members of the Council. The Education Committee would present a report on the results obtained by raising the standard of the preliminary examinations conducted by the College of Preceptors in England, the Educational Institute of Scotland, and the conjoint board of the Royal Colleges of Physicians and Surgeons in Dublin. The same committee would also report as to the answer given by them to the British Medical Association on the questions appertaining to preliminary education raised by the deputation of members of that association which was received by the Education Committee on behalf of the Council during the May meeting The proceedings of the international conference for the unification of the Pharmacopœial formulæ of potent drugs and preparations, held at Brussels in September last, had been reported on by the chairman of the Pharmacopœia Committee, who, by the authority of the Council, was nominated as a delegate thereto. Eighteen European Governments and the United States of America were represented by specially-appointed delegates, the British representatives being Dr. MacAlister, nominated by the Council, and Surgeon-Lieutenant-Colonel Reid, nominated by the Government of India. Certain important conclusions were unanimously adopted, with the object of eliminating, by means of an international agreement, the dangers to life and health arising from the wide differences which existed in the various national Pharmacopœias as regards the potency and strength of dangerous drugs called by the same or similar names. It was further resolved to request the Belgian Government, which had so laudably interested itself in this question, to establish in Brussels an international bureau of information and intercommunication, with the purpose of promoting uniformity of action among the authorities which control the Pharmacopœias of the countries represented at the conference. Dr. MacAlister's report would be referred to the Pharmacopœia Committee for consideration; meanwhile, he had received from the Lord President of the Privy Council an expression of thanks for his services as the representative of the British Government. In conclusion, he expressed regret at the fact that several practitioners had had to be summoned to appear before the Council for the investigation of charges brought against them—two being in respect of criminal convictions and the others for alleged professional misconduct.

Dr. **McVail** said that Dr. MacAlister and the President deserved great credit for having caused to be inserted in the Midwives Act the clause which made it penal after April 1, 1910, for any woman habitually and for gain to attend women in childbirth otherwise than under the direction of a qualified medical practitioner unless she was duly certified under the Act.

On the motion of Dr. **MacAlister**, seconded by Mr. **Bryant**, the thanks of the Council were voted to the President for his address, which was ordered to be entered on the Minutes.

After receiving *in camera* a report from the executive committee in regard to certain applications for the restoration to the *Medical Register* of names removed under section 29 of the Medical Act, 1858, the Council adjourned.

SECOND DAY.—Wednesday, November 26th.

Sir **William Turner**, President, in the chair.

Before proceeding with the ordinary business, Sir **Victor Horsley** obtained leave to give an explanation with reference to a statement made by Dr. McVail on the previous day. That statement, which was inaccurate, had been reported in the *Times*, and he wished to correct it in the interests of the British Medical Association. Dr. McVail had stated that the special clause in the Midwives Act which gave that Act a sense of reality, and not that of a sham, was due to certain members of that Council by their interest and work when the measure came before the House of Lords. None of those statements were altogether correct. The penal clause to which Dr. McVail made reference was drafted by the British Medical Association six years ago. It was brought by the British Medical Association under the notice of the promoters of the Bill. They embodied it in their Bill of 1901, but they left it out of their Bill in 1902. When they introduced the Bill into the House of Commons the British Medical Association through its committees again brought the matter forward, and by the assistance of Mr. T. P. O'Connor and Dr. Ambrose procured the insertion of the clause while the Bill was passing through the House of Commons.

Dr. **McVail** said that what he said was not meant to imply that no others in the profession had taken an interest in the matter. All that he said was within his knowledge—namely, that two of the principal members of the Council had taken an exceedingly important part in it, and he expressed his opinion, which he still held, that but for their action the matter would not have been given effect to.

Sir **Victor Horsley** said that Dr. MacAlister's points were founded entirely on the report of the Midwives Bill committee of the Council presented in April, 1898.

The Council was occupied for the remainder of the day with the consideration of disciplinary cases.

Alfred Hunter Goodwyn, L.R.C.P., L.R.C.S.Ed., L.F.P.S.G.

Mr. Alfred Hunter Goodwyn, of Budleigh Salterton, Devon, was brought before the Council, having been sentenced to a term of imprisonment for stealing jewellery. It was urged for the defence that he was not engaged in the practice of his profession at the time and that he had only been guilty of "larceny as a bailee," and that he was not really accountable for his actions.

After deliberating *in camera* the Council ordered his name to be erased from the *Medical Register*.

James William Ayres, L.R.C.P.Ed., L.S.A.

Mr. J. W. Ayres, of Liverpool, came before the Council in consequence of his having been sentenced to four months' imprisonment for manslaughter. He appeared in person and read a statement, in which he narrated the circumstances and urged that the occurrence was of the nature of an accident. The deceased man had, it seems, come to his surgery in a state of drunkenness and had declined to leave when ordered to do so Mr. Ayres consequently ejected him. Finding that the man had left his hat he took it out to him, and in a scuffle that ensued the man fell and struck his head against the kerb. He was taken home, but was not undressed or medically attended for six days, when he was removed to the hospital, where he died ten days later. Post-mortem a fracture of the sphenoid bone was discovered, but there was also advanced kidney and mitral disease. Mr. Ayres urged that the fracture might very well have been caused by his falling off the sofa, and appealed to the Council not to condemn him to what he said would be a "living death."

After a long deliberation *in camera* it was announced that the Council did *not* see fit to remove his name from the *Register*.

In another case, as the defendant is actually under restraint in an asylum, the Council decided not to proceed further with the inquiry.

Edward John Smith, M.R.C.S., L.S.A.

Mr. E. J. Smith, Balsall Heath, Birmingham, was summoned to answer a charge of having sought to attract practice by a system of extensive public advertisements of a character discreditable to a professional medical man.

Mr. Smith appeared in person, attended by his counsel Mr. Shultless Young. The case for the Medical Defence Union was conducted by Dr. Bateman.

Dr. **Bateman** described the case as one of systematic canvassing, touting, and advertising. The defendant had been written to in April, 1902, informing him that complaints had been made, and asking whether certain circulars had been issued by his authority, but no reply was received. A subsequent letter also failed to elicit a reply, whereupon the matter was brought before the Council.

Mr. **Smith** entered the rostrum, and admitted having sent out the circulars in question. They were sent out at a time when he was making between 150 and 180 visits a week, and they were sent out purely as a matter of charity, and, as a matter of fact, he lost money thereby. The circulars were only given to the very poor, and in the first instance the invitation was gratuitous. Last winter was the third winter he had issued these circulars. He complained that his letter to the Registrar of the Council had remained without a reply for four months, whereas an immediate reply would have enabled him to explain everything.

The **President** pointed out that he had been written to on June 16th, and had not replied, on which the defendant said that until he received the particulars in October he did not know what the charge was. He found he could not afford to attend these poor people for nothing, so had made a charge of threepence. His idea in imposing the charge of threepence was to limit the numbers.

After replying to various questions the defendant gave place to his counsel, who urged that there was a fair presumption that Mr. Smith did not intend to advertise at all. He had entirely confined his circulars to the very poor, from whom he expected no return, and he urged the Council not to discourage Mr. Smith from giving gratuitous treatment to the poor and suffering. If, however, the Council were of opinion that the practice was objectionable Mr. Smith would discontinue it.

Dr. **Bateman** pointed out that Mr. Smith had "ground baited" the district for two years with offers of gratuitous treatment, and had then issued his "threepenny circular." He urged that this conduct was "infamous in a professional respect."

After deliberating for a long time *in camera* the **President** announced to Mr. Smith that the charges brought against him had been proved to the satisfaction of the Council; that they took a very serious view of his conduct, and that, in order to give him an opportunity of reconsidering his position, they had adjourned the further consideration of the case until next Session, when he would have to appear and satisfy the Council as to his conduct in the interval.

THIRD DAY—THURSDAY, NOVEMBER 27TH.

Sir WILLIAM TURNER, President, in the Chair.

This was a *dies non* so far as the public business of the Council was concerned. The whole afternoon was devoted to an inquiry conducted *in camera*, with the concurrence of the defendant, into the conduct of William Arthur Jones, L.S.A., L.R.C.S.I., of Albany Road, S.E. The charge bore on the alleged criminal action of the defendant in procuring abortion in two specified instances.

After deliberation, the President announced that Mr. Jones had been adjudged guilty of "infamous conduct in a professional respect," and that his name had been ordered to be erased from the *Register*.

The Council then adjourned.

FOURTH DAY.—FRIDAY, NOVEMBER 28TH.

Sir WM. TURNER, President, in the Chair.

Sir VICTOR HORSLEY asked the President why no observations have been received from the Royal College of Surgeons of England and the Royal College of Physicians of London upon the Report of the Visitor and Inspector on the first examination of the Conjoint Examining Board in England furnished to the Licensing Bodies on October 7th, 1902.

The PRESIDENT said he was unable to give the information asked for, but referred him to Mr. Bryant on behalf of the Royal College of Surgeons and to Dr. Norman Moore on behalf of the Royal College of Physicians. These gentlemen stated that the matter was under the consideration of their respective Colleges, and that as soon as the report was complete it would be forwarded to the Council.

Dr. NORMAN MOORE asked whether any arrangements would be made during the present session as to the continuation of the visitation of the examinations in chemistry, physics, and biology held by the several licensing bodies, which on February 26th, 1902, it was resolved to carry out.

The PRESIDENT replied that no persons had been appointed to report on the primary examination.

Sir VICTOR HORSLEY called attention to a new synopsis issued by the Conjoint Board which was to come into force in May, 1903, and of which the Council was not officially informed.

Dr. NORMAN MOORE said that all alterations in regulations were submitted to the Council, but the synopsis was not yet in print.

REPORT OF EXECUTIVE COMMITTEE.

The Council continued *in camera* the consideration of a report from the Executive Committee in regard to certain applications for the restoration to the *Medical Register* of names removed under Section XXIX. of the Medical Act (1858). On readmission of the public the President announced that the Council had adopted the recommendation of the Executive Committee to remove the qualification of M.R.C.S.Eng. appended to the name of George Pearse Sargent from the *Register*, his membership having been determined by the College for advertising.

Mr. Sargent is still registered as L.F.P.S.G., M.D.St. And., and L.S.A.Lond.

THE PREVENTION OF PERSONATION.

The Council proceeded next to consider the report from the Committee for Prevention of Personation, and Sir VICTOR HORSLEY observed that Dr. MacAlister had made a very important suggestion in reference to the identification of practitioners and students—viz., that in addition to the forms of application being written in the handwriting of the applicant, they should also contain the date and place of his birth.

When Schedule I. came to be discussed Dr. BENNETT suggested that some term other than "Christian name" be used, since this, he suggested, might be objected to by Jews. The President advised "prénom." Among other substitutes suggested were "forename," "personal name," "individual name," "additional name." The President remarked that in Edinburgh, where there were a great many Indian students, it was difficult to tell where their names began and their titles ended.

After some discussion it was decided that the heading "Christian and surname" should be removed from the schedule, and in lieu thereof the term "full name" employed. Recommendations were then agreed to by the Council to the effect that (1) No registration on the *Students' Medical* or *Dentists' Registers* shall be effected unless application be made upon forms supplied by the Registrar. (2) That all forms of application for registration, duly signed, shall be preserved by the Registrar of the Branch Council in such manner as to be easily accessible for reference. (3) That all applications for restoration to the *Medical or Dentists' Register*, or for registration in these *Registers* under exceptional circumstances, shall be accompanied by a statutory declaration furnished upon a form supplied by the Registrar.

The report was adopted, and the PRESIDENT thanked Sir Victor Horsley for having brought it to a satisfactory conclusion.

The next item of business was the report on the case of James Dixon Goy by the Dental Committee. An inquiry was held on November 22nd, 1902, at which Mr. Goy did not appear personally or by representative. It having been established that he had used the qualification L.D.S., R.C.S., without any right, his name was directed to be removed from the *Dentists' Register*.

FIFTH DAY.—SATURDAY, NOVEMBER 29TH, 1902.

Sir WM. TURNER, President, in the Chair.

The Council proceeded to discuss the proposed

MEDICAL ACTS AMENDMENT BILL.

This Bill has for object the carrying out of the financial reforms recommended by the Financial Relations Committee. The Bill provides for the receipt and administration of all funds and the appointment and payment of all officers by the General Council (except that the Registrars of Branch Councils are to be appointed on the nomination of the Branch Council), for an increase of the fee payable on registration and for the payment of a fee by students for entry of their names in the *Students' Register*.

Sir VICTOR HORSLEY moved (seconded by Sir Christopher Nixon) that a report be prepared of the financial position of the council to be submitted to the Privy Council. Thereupon Dr. NORMAN MOORE rose to object, urging that before asking the public for more money the Council ought to prove that economies could not be effected. He went on to say that if, instead of five guineas a day members of the Council were paid three guineas or nothing at all, the public would look upon that with complacency, and the members might do so with propriety.

Dr. MCVAIL pointed out that it was premature to discuss the matter, and moved as an amendment that the consideration of the motion be postponed.

It was then moved by Sir VICTOR HORSLEY, and seconded by Sir CHRISTOPHER NIXON, that the Council should go into committee to consider the clauses of the draft of the Bill. Sir Victor explained that all the proposed alterations had one object in view, viz., that of the consolidation of the Council's finances.

The second clause of the Bill provides for the lack of income by raising the registration fee from the previous sum of £5 to a sum not exceeding £10. Clause 4 had for object to obtain statutory authority to compel the registration of students, the fee on registration of a student to be £1.

Moved by Sir VICTOR HORSLEY, and seconded by Sir CHRISTOPHER NIXON, and subsequently carried, that Sub-clause 1 of Clause 1 read: "that the General Council may from time to time appoint such person as it shall think fit to be Registrar of the General Council, and may remove any person so appointed."

Sir VICTOR HORSLEY, seconded by Sir CHRISTOPHER NIXON, moved the adoption of Sub-clause 2: "That each Branch Council may from time to time nominate a person to be appointed Registrar of the Branch Council; and the General Council, if it approve of the person so nominated, shall appoint him to be Registrar of the Branch Council. The Registrar of a Branch Council may be removed by General Council.

Dr. MCVAIL objected to the sub-clause on behalf of the Scotch Branch Council, on the ground that it was a slight on the Branch Council, and that the latter should have the right to appoint its own Registrar.

Sir VICTOR HORSLEY pointed out that the body which paid the salary should have the right to veto the nomination, though of course this was not likely to happen.

Dr. LITTLE expressed surprise that a practical Scotchman should object to such a sensible arrangement.

Dr. BENNETT, speaking as President of the Irish Branch Council, agreed with Dr. McVail, and suggested that they should do away with the Branch Councils, as their *raison d'etre* was being taken from them.

Sir CHRISTOPHER NIXON suggested a way out of this difficulty by giving the Branch Council the right of suspension.

Dr. ATTHILL reminded them that the General Council was powerless to force on the Branch Council a Registrar not approved of by that body.

After some further discussion the sub-clause was agreed to in its full and amended form:—"That the Registrar of the Branch Council may be suspended by the Branch Council and removed by the General Council."

Sub-clause 3, dealing with the appointment of the treasurer of the General Council and his tenure of office was carried, but Sub section 4, bearing on the appointments of additional officers, including clerks or servants, was postponed, in order that the legal adviser of the Council might be consulted. Sub-clause 5, providing for the payment of salaries, was then adopted.

Discussions on Sub-section 6 postponed till Monday, when the Council can confer with Mr. Muir Mackenzie.

In reference to Clause 2, the main object of which is the centralisation of all funds of Branch Councils into one general fund, that of the General Council, Dr. McVAIL urged that making the three funds into one would not increase the amount at their disposal. Where real economy could be effected, he observed, would be by delegating to the Branch Councils some of the work at present done by the General Council; in this way the latter might conceivably be enabled to complete its business in three days.

Dr. ATTHILL asserted that no members would sit for the Branch members' fee of two guineas. He pointed out that the Irish Branch Council had no funds at its disposal, so that when Dr. McVail referred to the three funds being made into one he must have overlooked the difficulty of transferring nothing.

In reference to the clause respecting the proposed increase of the registration fee to a sum not exceeding £10, Sir VICTOR HORSLEY pointed out that the sum need not necessarily be £10; it might be something under, say, £7. This was agreed to. The Council adjourned till Monday.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, Nov. 30th, 1902.

ABDOMINAL AORTITIS.

PROF. TEISSIER spoke before the Clinical Society on inflammmation of the abdominal aorta as first described by Prof. Potain three or four years ago. After relating the cases of some patients treated in his hospital service, the speaker passed in review the etiology and symptomology of the affection. Primary or idiopathic aortitis were exceptional, yet cold might constitute a factor. The aortitis was most frequently *propagated*, that is to say, consecutive to an extension of inflammation affecting the upper section of the artery or that of a neighbouring organ (kidney, biliary vesicle, and, above all, the intestines). Infection, such as that of *grippe* or tuberculosis, could certainly be considered as a direct cause. Typhoid fever, syphilis, malaria, or saturnism have been incriminated, but he had not met with a case that could be fairly attributed to any of these maladies.

The cardinal symptoms of abdominal aortitis had been fully described by Potain, epigastric pain, rachialglia, irradiating pains in both flanks, palpitations, &c., these form the subjective symptoms, while the objective consist essentially of three: *pain provoked* over the aorta and the iliac arteries, *deviation of the vessel*, and *mobility*

The pain could be very intense; was localised to the vascular walls, and could be continued along the iliac arteries to the inguinal regions, a fact of great importance. The aorta was frequently deviated, became curved and sinuous, forming an arc, with the concavity turned towards the vertebral column. At the same time the vessel became mobile by reason of the laxity of the cellular tissue.

As symptoms corollary he would mention pulsation in the epigastrium, a *bruit de souffle* perceived by the stethoscope, particular position of the patient in bed (knees drawn up and decubitus on the side), severe contraction of the rectus muscle frequently giving sensation as of a tumour in the epigastrium.

When the three essential symptoms were present—pain on pressure, deviation, and mobility—the case presented no difficulty. However, it sometimes happened that, in spite of careful examination, the diagnosis was not satisfactorily demonstrated; in such cases he had obtained considerable assistance from the sign of the anterior tibial artery. Where hypertension was discovered in that vessel, as contrasted with the degree of compression of the radial artery, it proved absolutely that the sub-diaphragmatic vessels were in a state of irritation and the diagnosis of abdominal aortitis was presented, but when the tibial artery was in a condition of hypotension, then the symptoms complained of by the patient might be fairly attributed to one of the complex affections inherent to neuropathy. For the speaker, the sign of the tibial artery was almost pathognomonic. The treatment would be—rest in bed, gentle diet, poultices or blisters, according to the degree of intensity of the malady. Applications of belladonna ointment, enemas of bromide of ammonium to calm irritation of the intestines. Internal medication was always necessary, and consisted in preparations of iodine and tannin, and, perhaps, small doses of calomel.

ZONA.

Paint the vesicles with salicylate of methyl morning and evening and apply oil silk. Relief and cure rapidly obtained.

MORTALITY IN THE FRENCH ARMY.

French military hygiene is evidently not altogether up to date. According to a recent statement of the Minister of War, the mortality per annum in the army is 2174, as compared with 741 in the German army. This means that since the Franco-German War the French have lost from disease 99 000 men, while the Germans have only lost 13,000 men. No wonder the Minister "deplores" the sanitary conditions which prevail in military life. The principal causes of death are typhoid fever, scarlatina, and tuberculosis.

THE opening meeting of the Dublin University Biological Association was held on Thursday last, when the newly-elected President—Dr. T. P. C. Kirkpatrick — delivered an inaugural address on "Consumption and the Public Health."

Germany.

[From our own Correspondent.]

Berlin, November 29th, 1902.

At the Medical Society, November 5th, Hr. Baginsky discussed the question of

Antistreptococcus Serum in Scarlatina.

He reminded his hearers that in 1892 he had made the observation that when scarlatina occurred as a complication of diphtheria the diphtheria bacillus disappeared from the fauces, and its place was taken by the streptococcus. If this occurrence was not altogether constant it was at least very frequent. He had examined 696 cases of scarlatina bacteriologically, and had always found streptococci, mostly in company with other bacteria, such as staphylococci, diplococci, Loeffler's bacillus, and many others. From the frequency of the occurrence of streptococci in the disease he drew a certain significance of the one for the other, and believed that the streptococci were not to be looked upon as secondary. Nothing more specific could be found in streptococci cultivated from those found in the mouths of scarlet fever cases.

Aronson had prepared an immunising serum from streptococci which the speaker was himself convinced possessed strong immunising properties and did no harm whatever.

Although earlier attempts to treat scarlatina with Marmorek's antistreptococcus serum had failed, he proceeded to take them up again with Aronson's new serum.

In order to obtain information as to the mortality of scarlatina, he had compared the rates for different years and ascertained that they were subject to the most extraordinary fluctuations without its being possible to discover any explanation for this.

The slight difference in the mortality between those treated with serum and those not (11 to 14 per cent.) was of no value in arriving at a conclusion. He first injected 20 cc.m. and repeated this according to requirement until six times the quantity had been given. In January he only treated four bad cases with these high doses, in which not only no improvement was demonstrated, but the speaker was glad that the children overcame the effects of the injections. After an interruption, however, he recommenced his attempts at treatment, and this time the serious and alarming effects did not appear. The character of the epidemic had, however, not apparently altered, but Aronson had succeeded in preparing a stronger serum, and in arranging a more accurate dosage.

Without the fall of temperature having anything characteristic about it, on the third or fourth day after serum treatment in uncomplicated cases, and from the fifth to the sixth in cases not so treated, he then believed the serum had an action. He was in a measure able to dominate the disease, not in so *éclatant* a manner as diphtheria with diphtheria serum, but certainly better than before.

A sudden euphoria, such as Escherich observed after the injection of Moser's serum he had not seen himself. This observation showed, however, that even that serum was active, although prepared in a different way (without previously passing through animals).

Hr. Menzer observed that he had seen articular rheumatism run a more severe course in winter than in summer, and he considered it possible that the absence of severe cases was due to the time of the year.

Hr. Aronson reminded the Society that with increasing concentration of the serum the results had been better. In the case of serum prepared without passing through animals exact dosage was impossible.

Hr. Baginsky, in reply, maintained that the serum had become better instead of the cases showing more favourable symptoms.

The Dutch Treatment of Epilepsy.

(*Neurol. Cuol.*, 17, 1902). Dr. Hubert Schintzer writes in the paper named that the inmates of the Kückenmüller Institution, Stettin, have the following diet: 1½ litres of milk, 20 grm. butter, 3 eggs, 400 grm. bread-fruit, either uncooked or cooked, sodium chloride about 2 grm. The bread, instead of being baked with salt, is made so that the daily allowance of 400 grm. contains 3 grm. of sodium bromide. The following results were obtained In two cases the attacks ceased the whole period of the experiment (forty-two days); in ten cases there was very considerable improvement; and in two no improvement was noted. In most of the cases the severity of the attacks was considerably diminished.

The results are worthy of note, even if they do not equal those of Bálint. The patients do not submit to the diet for long. The writer advises that in treating epileptic cases a period of six to eight weeks should be occasionally put in when the above-named method of treatment should be carried out.

Bromipine.

Dr. Joh. Kejzlar (*Kl. Therap. Wochensch* 39/02) recommends bromipine as a good and useful remedy in condition of nervous excitement, especially with the nervous palpitation of neurasthenics, in whom the administration of a teaspoonful of a 10 per cent. solution of bromipine will induce sleep. It is also useful in hysterical attacks, in nervous sleeplessness and giddiness, as well as in infantile convulsions. The taste was rather disagreeable, but it could be given in hot milk, sweet wine, or in capsules.

Austria.

[From our own Correspondents.]

Vienna, November 29th, 1902.

Lympho-Sarcoma.

At the "Gesellschaft der Aerzte," Sternberg showed the organs and blood preparations taken from a case of lympho-sarcoma in the anterior mediastinum, associated with leucocythæmic enlargement of the spleen and liver. In the brain at the post-mortem were found numerous blood clots about the size of beans, while the marrow of the long bones was of a dark red.

The patient, fourteen years of age, was a bookbinder's apprentice, and on account of an increase of the size of his abdomen and difficulty of breathing was received into hospital. On admission the spleen was found to be considerably enlarged, with great tenderness, or rather pain, over the long bones and sternum.

The temperature ranged about 38° Centigrade (100 4 Fahr.) The leucocytosis of the blood was very pronounced, being as one to two, more particularly in respect of the mononuclear cells or lymphocytes.

Hitherto we have been in the habit of diagnosing this condition of the blood as leucocythæmia, but from the light shed on the subject recently by Drozdu, this view must be accepted with caution.

Drozdu's case bears a close resemblance to the above, and was carefully observed for eight days. There was a lympo-sarcoma, and the blood was typical of leucocythæmia.

These cases are particularly interesting from the pathological combination of lympho-sarcoma with leucocythæmic changes in the liver and spleen.

Kretz related a similar case, that of a patient whom Paltauf had exhibited at the Dermatological Congress in 1892. The patient was suffering from lymphodermia, with all the hæmatic conditions of lymphatic leucocythæmia.

Foreign Body in Larynx.

Chiari next showed a triangular piece of charcoal, measuring two and a-half centimetres in length, two in breadth, and one in thickness, which he had taken from the throat of a child, æt. 5. The child had been eating spinach on September 23rd, when suddenly something stuck fast in the throat, setting up a violent cough that caused blood to flow profusely. As there was considerable pain and difficulty in breathing it was resolved to perform tracheotomy. On trying to introduce the tube into the upper part of the trachea no passage could be effected, so the patient was again narcotised and examined with the laryngoscope, but without success. At last the Röntgen rays were requisitioned, and the obstructing body seized with a long pair of forceps and extracted through the wound.

Grossman related a similar case where the foreign body swallowed was a piece of bone, which caused great pain and dyspnœa, but was finally coughed up, to the great relief of the patient.

Deceptive Impressions.

Urbantschitsch next delivered a lecture of a rather metaphysical character on the relationship of sight, sound, and touch sensation. He showed that moving bright lines or a number of points would produce a peculiar sensation; a monotonous tone will produce a particular image, and irritation of any organ of touch gave rise to the perception of certain sounds. Coloured surfaces will also act on the acoustic apparatus and produce the sensation of particular sounds.

Splenic Eversion.

Later Budinger showed female, æt. 37, on whom he had performed splenectomy for twisting at the pedicle. This accident took place quite suddenly, without any severe straining to account for its production. The spleen had revolved 180°, so that the internal margin had become external. The spleen was replaced and secured, and the patient made an excellent recovery.

Zuckerkandl referred to the etiology of these floating spleens, and remarked that the wonder was we had so few of those malformations considering the history of the organ. In a normal condition the pancreas and the spleen are evolved from the fœtal mesogastrium, and about the fourth month of fœtation it appears in the posterior region of the abdomen, where the spleen and pancreas arrange and fix themselves. For a time after this the growth of the organ is suspended while left hanging to the mesentery, when the slightest movement might cause displacement.

Ullmann related a similar case of splenic torsion, for which he had performed splenectomy two years ago. In his case no such conditions as Zuckerkandl had related were the cause, as the patient had suffered from malaria and had a very large spleen in consequence. After contraction, the spleen was found to wander away to the right side, and subsequently become twisted, rendering an operation necessary owing to the tenderness and extreme pain in the right hypochondrium. Three weeks after the operation the patient left the hospital perfectly well. Several weeks after her discharge she died from the effects of sepsis after criminal abortion, when the post-mortem showed that the operation had been perfectly successful.

Latzko demonstrated a case that supported the inhibition of growth referred to by Zuckerkandl. The spleen had been retained in the pelvis along with the pancreas. Along with the spleen was found a hæmorrhagic cyst about the size of a child's head.

The Operating Theatres.

GUY'S HOSPITAL.

Operation for Deformity Consequent on Separation of the Lower Epiphysis of the Radius in a Child, a Condition commonly Regarded as Constituting one of the Varieties of Colles's Fracture.—Mr. Arbuthnot Lane operated on a child, æt. 8; the fracture had taken place three weeks before admission, and had been treated in the usual manner, namely, by some form of manipulation and by a mechanical arrangement which, Mr. Lane said, goes by the name of Carr's splint. The resulting deformity and disability were great, especially the deformity, which was most distressing to the parents of the child. The fracture was freely exposed from the outer side, when a sharp, thin chisel was introduced through the junction of the displaced epiphysis and shaft, and the junction was cut through; the lower end of the shaft was then thoroughly freed from the surrounding soft structures, and with much difficulty brought into its normal relationship to the epiphysis; being retained in position by means of a rod of thick silver wire.

Mr. Lane pointed out very strongly the utter folly of treating these cases of separated epiphyses of the lower end of the radius by manipulation and splints, unless perfect adaptation of the fragments can be effected. This applies also, he said, to the treatment of Colles's fracture in active adult life; in old age the comminution of the lower fragment is so considerable that an operation is more rarely required and offers fewer advantages. In separation of epiphyses, he remarked, callus is thrown out in abundance at a very early date, and if an operation is required the earlier in the history of the case it is performed the better. After two or three weeks have elapsed the difficulties that have to be met, and the demands on the skill of the operator, are very great. He had recently called attention to these points in a paper in the *Practitioner*, in which he had shown that if the displacement is not rectified, the whole length of the shaft alters in character, an entirely new one replacing that which previously existed. This most interesting experiment shows, he said, that the skeleton is the crystallisation of the lines of force, those running in varying directions being laid down as cancellous tissue, and those in one direction as compact tissue; also that any alteration in the normal mechanical relationship of the organism to its surroundings is followed by corresponding alterations in the anatomy of the skeleton, these changes taking place in a degree inversely proportional to the age of the subject, this being particularly the case in infancy.

The subsequent progress of the case was most satisfactory, only a slight difference being observed at the end of a month between the two hands.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

EXTREME CASE OF CONGENITAL TALIPES. — Mr. ARBUTHNOT LANE operated on a child, æt. 8; the case presented very considerable deformity, the sole of the foot being turned inwards and a bursa having formed upon the outer surface of the cuboid and fifth metatarsal. There was present a scar in the hole of the foot extending from the internal malleolus to the base of the fifth metatarsal bone, along which line all the soft parts had been divided down to the bones. There was no evidence to show why this operation had afforded no advantages to the child. Mr. Lane came to the conclusion that the only way in which the sole of the foot could be made to perform its normal functions was by the excision of the cuboid; this was accordingly done; the base of the fifth metatarsal was wired to the outer surface of the os calcis. The foot was retained securely in position by means of a plaster of Paris arrangement. The result of this operation, in so far as the form of the foot was concerned, was very remarkable; it certainly, Mr. Lane said, had none of the extreme mechanical disadvantages which follow division of all the soft parts of the sole of the foot by an open incision. Mr. Lane urged most strongly that all cases of talipes requiring operation, or likely to require operation, should be suitably operated on the day after the child is born. He considered the present plan of postponing operative interference for two or three months as unscientific and ridiculous in the extreme.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d.; Half Page, £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 3, 1902.

THE GENERAL MEDICAL COUNCIL.

THE session which has just come to an end has been conspicuous by the absence of any particularly "burning" topic for discussion, The Midwives' Bill, having become law, ceased to possess any interest for the Council, and no opportunity was afforded for resuming the debate on the attitude of the Royal Colleges towards the Council's remonstrances. The list of penal cases was heavy, but none of them possessed any particular interest. One practitioner hailing from Birmingham was found guilty of discreditable advertising, and with a leniency which is not altogether easy to understand, the Council allowed him six months in which to reflect upon his conduct with a view to reform. The revised scheme for the prevention of personation on the part of persons applying for registration in the *Students'* and *Medical Registers* has been brought to a satisfactory conclusion, and the thanks of the profession are due to Sir Victor Horsley for having carried through this important reform. It would be too sanguine to suppose that the offence of personation has thereby been rendered impossible, but at least it has been made much more difficult and less liable to escape detection. The most important subject before the Council was the draft of a bill to amend the existing Medical Acts in order to enable the Council to carry out the financial reforms recommended by the Financial Relations Committee, the principle of which was approved by the Council in May last. The Bill proposes to give the General Council greater powers in respect of the Branch Councils, and to throw the funds hitherto allocated to the latter into the general fund. As Dr. McVail humorously pointed out, this will not of itself remedy the penury with which the Council is threatened, especially as in the case of the Irish Branch Council there are no funds to transfer:

> "For optics sharp it needs, I ween,
> To see what is not to be seen."

The next step, therefore, is to provide the sinews of war, and the means to be adopted will take the form of an increase in the fee paid on registration from five pounds to a sum not exceeding ten pounds. It may be taken for granted that the Council would not avail itself of this latitude, when accorded by Parliament, to impose the maximum sum forthwith; indeed, seven pounds was suggested as a suitable beginning. This device will leave the Council in possession of a margin which can be impinged upon should the duration of the sessions undergo further indefinite extension with a corresponding increase in the expenses attendant thereon. As there exists a doubt as to the power of the Council to insist upon the registration of students, a clause is introduced to make it compulsory, thus providing the desired opportunity of mulcting the aspirant student to the sum of one pound. No objection can be taken to this moderate impost, which has the merit of tapping a new source of revenue, and conjures the bogey of an annual contribution to the funds levied on practitioners already on the *Register*. No mention is made in the draft Bill of any provision to establish the right of the Council to decide and regulate the vexed question of the scientific education of medical students, and no doubt this omission is based on the hope that the Royal Colleges may come to terms.

REFORMS IN LUNACY LAW.

The study of insanity is one of practical importance to every practitioner of medicine of whatever rank or standing throughout the Empire. Happily it has advanced steadily in the path of humanity, as well as of enlightenment, in common with other branches of applied medical science. The problem of how to deal with persons of unsound mind is obviously beset with many difficulties, not the least of which arise from the social disability that unfortunately attaches itself in the mind of the public to the mention of the words "insane" and "lunatic asylum." The history of the treatment of the insane in this country has shown clearly that there are two widely differing sides to the question, namely, the scientific and, what may be called for want of a better term, the social or legal, or medico-legal. There can be little doubt in reference to the latter section that the experience of the purely scientific worker, valuable as it is from many points of view, is only of indirect value in modifying the wider issues involved in the interference with the liberty of the subject by compulsory detention of certified persons within the walls of a public or a private asylum. The constant care of the Legislature has been to safeguard the liberties of the subject by such machinery as certificates, registration of persons receiving insane patients, and periodical official inspection. Some aspects of the wider question have been recently dealt with by Sir William Gowers in the address delivered before the Medico-Psychological Society of Great Britain and Ireland. His main thesis appeared to rest upon the advocacy of a more elastic system, whereby persons of unsound mind might be received into the houses of persons paid for their care and maintenance, but without the brand of certification. He also advocated the extension of control over many doubtful or "borderland" cases. This additional power he would place in the hands of medical men by a system of notification which would not necessarily involve detention. The suggestion is worthy of the most careful attention, even, as suggested, at the hands of a Royal Commission. At the same time the fact cannot be lost sight of that without the imposition of stringent safeguards the substitution of notification and the opening of the doors of unlicensed private lunatic asylums would be to resuscitate some of the potential conditions on which were founded the grave abuses that undoubtedly existed in private asylums at no very remote period of time. The proposal for a scheme of compulsory notification of unsoundness of mind offers many attractive features. In our opinion, however, to be effectual it would have to be combined with a public lunatic asylum service fitted for all ranks of the community. On the private asylum hinges almost all the potential possibilities of evil in the treatment of the insane, and it is to the abolition of private asylums that we look hopefully for the first fundamental step in the reform of lunacy law. The interests concerned in that particular class of institution throughout the Kingdom amount to a vast aggregate, but that consideration is hardly likely to have influenced the views of a man of such known independence of character and clearness of thought as Sir William Gowers. It is interesting to speculate how so important a question as the nationalisation, so to speak, of our asylums for the insane could have escaped mention in his recent valuable contribution. Meanwhile, the attention of the medical profession, as well as of the public, has been further drawn to the matter by experts who have stated their individual views freely enough in the correspondence columns of the *Times* and other journals. Reform of lunacy law is one of the many social matters that has long been in need of drastic and enlightened revision.

MR. JUSTICE BIGHAM AND THE N.S.P.C.C.

The price of popular safety, to paraphrase a famous saying, is eternal vigilance. The administration of justice in this country is happily of the purest, but for all that it is impossible to deny that existing blemishes demand the skilful and timely application of the legislative pruning knife. A court of criminal appeal, for instance, and a readjustment and greater consistency of penalties are reforms that loom large in the near foreground. It remains to be seen what is to be done with judges who lose their tempers or who substitute forensic advocacy for the judicial function. We should be extremely sorry to attribute even remotely any such lapses from official dignity to so distinguished and justly respected a judge as Mr. Justice Bigham. At the same time we venture to think that he has somewhat exceeded the bounds of prudence in his attitude at a recent trial with regard to the National Society for the Prevention of Cruelty to Children. Whatever may be the faults of that body, it is nevertheless beyond question that they have effected an enormous amount of good. On the principle that so many laws argue so many sins, we may infer from the existence of the Society that a great social evil exists in the shape of cruelty to children. The organisation has, indeed, been created in order to protect a peculiarly helpless section of the community. If the tree is to be judged by its fruit, then the Society has justified its existence a thousand times over. In the notorious Penruddocke case for instance, a revolting case of systematic cruelty of a child by parents of good social position would not have been brought to light had no such body existed as the N.S.P.C.C. It is with no little surprise, therefore, that we listen to Mr. Justice Bigham in a recent trial of a baker and his wife for the manslaughter of a child thirteen months old, who died of pneumonia, accelerated, if not actually caused by, starvation. The parents were miserably poor, and the father was admittedly a respectable working man. They were not defended by counsel, so that their case was very properly protected by the Judge. At the same time it is impossible to admit the implied censure of Mr. Justice Bigham on the practice of the working together of the officers of the Society and the coroner. Nor can we understand his ground in preventing a medical witness from stating the average weight of a child of thirteen months as against the actual seven pounds which was the weight of deceased. Such evidence has a distinct corroboratory value, especially when taken with the emphatic medical opinion that the accompanying emaciation was due to starvation. Mr. Justice Bigham may have been perfectly right in pointing out to the jury that it was necessary to sift the evidence of people appearing to support a prosecution to see that there was no exaggeration. The temper of the British public, however, may probably be trusted to exercise proper control over the actions of a vigilance society, which is supported by public charity for high and definite aims.

Notes on Current Topics.

The Function of the Flagella in Malarial Parasites.

As long ago as 1898 MacCallum published certain observations on malarial infection in birds, to show that the function of the flagella of the parasites was sexual. He noticed flagella breaking off from non-granular bodies, and then passing to and penetrating granular extra-corpuscular bodies. The latter, apparently being thereby fertilised, assumed the fusiform shape which is familiar under the microscope. He prophesied that probably the same series of events would be observed in human malarial blood, and a little later he was himself lucky enough to see it taking place. Although no one has ever cast doubt on MacCallum's accuracy, yet only once have other observers—Drs. Warfield and Paussent, of John Hopkins Hospital—verified his account by independent observations. In a recent number, however, of the *John Hopkins Hospital Bulletin* (October, 1902), Dr. Moore, of Texas, describes the same occurrence, which he saw while examining blood from a case of æstivo-autumnal fever. Happening to have a granular and a non-granular body within the field of the microscope at the same time, he noticed the pigment of the latter in very active motion, and in a moment four flagella were shot out One of these freed itself and plunged about until it came into contact with the granular body. After several efforts the flagellum entered the body. About the same time another flagellum became free, and also approached the granular body. For five minutes it seemed to be making unsuccessful attempts to make an entrance, but finally wriggled away. The other flagella also became detached, and were lost sight of among the red corpuscles. The granular body underwent certain changes in its shape and the arrangement of its pigment, but it was not possible to watch it long enough to observe the stages of its development. Nevertheless, we think that Dr. Moore's observation, taken along with the others quoted, is sufficient to establish the sexual character of the flagella of malarial parasites.

The Manufacture of Drugs.

In the matter of physic the modern man of medicine is provided with weapons of infinitely greater precision than those in the power of his ancestors, near or remote. The general improvement has been in great part due to the competition of trade, whereby rival manufacturers have been obliged to study the methods necessary to keep their products in the front rank. In no other way can the business of great wholesale drug manufacturers be established and maintained. Some of them have so far realised the value of standardisation that they themselves have in certain cases voluntarily fixed their own guaranteed standard of strength. The gain all round from this state of affairs cannot readily be estimated. For one thing, medical men are enabled to treat disease with trustworthy remedies, and may rely on their patients being supplied with what has been actually ordered. In the old days, when drugs were prepared by the dispensing chemist, it was impossible for him to keep a supply of all ordinary preparations, so in order to dispense a prescription he had often laboriously to commence by making some extract or tincture or decoction or other vehicle of pharmacology. Nowadays, however, all that is changed, and the smallest country chemist can maintain an ample array of first-rate drugs at a comparatively small outlay. The chief drawback to this Elysian horn of plenty is that the public are tempted to prescribe their own physic. After all is said and done, however, the man in the street, in nine cases out of ten, patronises the well-advertised patent medicines to the exclusion of orthodox drugs of the pharmacopœia.

The Modern Medical Thesaurus.

The vast accumulation of knowledge that has gathered, and is still fast gathering, around the fabric of modern medicine may well give pause to the mind of any mere mortal. It has long passed the limits of comprehension of any man, and the flowing tide of fresh discovery shows no sign of abating. The necessity for specialisation that has arisen from this state of affairs is manifest in every branch of the profession. Nowadays, even the general practitioner is wont to specialise in some particular direction, a proceeding that cannot fail to react favourably upon his practical attainments. Indeed, the really well-equipped specialist never loses touch with the wider aspects of his profession. In some distant future it seems not unlikely that a vast number of human maladies will vanish before the aggressive march of preventive medicine. It is most interesting to speculate on the enormous number of ailments that will be banished when science obtains the mastery over say, half a dozen communicable diseases, such as whooping-cough, enteric fever, influenza, measles, and summer diarrhœa. Happily, too, for the future man of medicine there is the certainty that every now and then some general law will be deduced from the vast mass of observations, whereby his labours will be lightened. Meanwhile the much-abused medical publisher does his best to make the path clear by the provision of a host o- systematic treatises on both general and special subjects.

The Sacredness of "Natural Methods."

Many minds bow in humility and adoration before what they are pleased to term "the Light of Nature," and accord to so-called "Natural Methods" such reverence and obedience as they willingly grant to "divine law." "Instinct" is trusted while instruction is decried. And in much confusion of thought advocates for natural methods not infrequently counsel a return to procedures worthy only of the savage and the beast. We are glad to find that Mr. H. G. Wells, in the November number of *The Cosmopolitan*, boldly attacks such a superstitious and sentimental attitude.which in certain quarters is forming a serious opposition to the beneficent application of scientific measures. It has long been a prevailing idea that with maternity came the necessary instincts for the protection and preservation of the new life. And still, in spite of all the ghastly evidence of the folly of such a contention, the old tradition exerts its fatal spell. The holocaust of children still goes on, and the massacre of the innocents is perennial. While political agitators scream hysterically regarding a totally unforeseen and unavoidable epidemic of measles which unfortunately proved fatal to some thousands of children in South Africa, they remain dumb when in that very same year more than twenty-one thousand little children die needlessly in Lancashire. Probably three-fourths of the children born in England start life handicapped, and fail to reach their highest development. They are born of mothers preoccupied by the necessities of earning a living, or by vain occupation, or already battered and exhausted by immoderate child-bearing; they are born into insanitary and ugly or inconvenient homes; their mothers or nurses are ignorant or incapable ; there is insufficient food or incompetent advice ; and with vitiated air and lack of sunshine they remain throughout life physically submerged. The light of modern medical science is used to dispel the dark shadows cast by the "Light of Nature."

Folk-Medicine in Ireland.

There are few more entertaining, though perhaps many more useful, studies for a medical man than that of the origin of his craft, and in particular of such remains of primitive medical lore as still linger in the form of popular remedies and treatment among the more ignorant and conservative of the people. And indeed, worthless as are most of the facts we come across, when considered in relation to modern medicine, yet we sometimes find that popular opinion has by many years anticipated science in the adoption of some useful therapeutic measure. For instance, the treatment of rheumatism by a decoction of willow bark was in use as a folk-cure in Ireland long before its active principle, salicylic acid, was used by the faculty for the same purpose. But folk-medicine is by no means dainty in its choice of medicaments, and we find that human and animal excrements have always held a large place in its pharmacopœia. Thus, as we learn from Colonel Wood-Martin's recent book, "Traces of the Elder Faiths in Ireland," cow-dung is in common use as a dressing for cuts and wounds in the west of Ireland, while human urine is used as a lotion in the same kind of injuries. A continued poultice of cow-dung has also the reputation of preventing pitting and scarring in small-pox. *Euthanasia* in hydrophobia has long been in use, and we have heard of a patient suffering from this disease being smothered with a feather-bed little more than ten years ago. Saliva has many therapeutic applications, and sore eyes are constantly treated by being licked by a person with "the gift." The cure in such a case was never effected without the recitation of the appropriate charm.

Exploratory Tapping in Suspected Abscess of the Liver.

In an interesting paper read before the last meeting of the Clinical Society Lieut.-Colonel Hatch uttered a well-deserved caution against the practice of making exploratory punctures in cases of suspected abscess of the liver. Very serious consequences not unfrequently follow this operation, especially in cases where the diagnosis of abscess ultimately turns out to be unfounded. The needle sometimes passes through the pleura, thus exposing the patient to the risk of empyema, or it may set up uncontrollable hæmorrhage in the congested liver substance. The suggestion made by experienced surgeons that it is better to make a small incision through the abdominal wall in order to see where the needle is introduced has much to recommend it. The caution is addressed to physicians rather than surgeons, because it is they who habitually resort to the needle in their endeavours to support a doubtful diagnosis. The proper application of this means of exploration is rather to localise exactly the position of an abscess the existence of which has already been established than merely to make sure of its existence.

The Penruddocke Case.

The recent notorious Penruddocke case, in which the wife of a county magistrate of good social position was convicted of gross cruelty to a child, presents various points of interest. The origin of the mother's harsh treatment of her daughter is to be found in the incontinence of urine from which the latter suffered. In the eye of the law, no less than of ordinary ethics, the mother was utterly unjustified by that fact in inflicting a long series of brutal punishments upon the child. Her first prompting probably arose from the mistaken view that the physical affliction was due rather to wilful carelessness and neglect on the part of the little one than to the functional or organic imperfection that really lay at the root of the matter. Hence she was perfectly logical, from her mistaken point of view, in adopting punishment as a means of correcting a condition that required patient and prolonged medical treatment. With other aspects of this remarkable case we are not so directly concerned. However, it may be well to note that but for the existence of the National Society for the Prevention of Cruelty to Children this prosecution would not have been forthcoming. That the mother should have been allowed to escape with a fine of £50 suggests that the penalties daily inflicted upon poor persons are disproportionately severe. *Mutatis mutandis*; any working man convicted of gross cruelty to a child should henceforth be permitted to commute his imprisonment by payment, say, of five shillings, which would be no more to him than fifty pounds to Mrs. Penruddocke. That the husband of the latter should be allowed to remain on the magistrates' bench seems hardly reassuring as to the future dispensing of justicial justice.

The Case of Mr. J. W. Ayres.

The decision of the General Medical Council in allowing the name of Mr. J. W. Ayres, of Liverpool, to remain upon the *Medical Register*, in spite of his having been sentenced to a term of imprisonment for manslaughter, will, we feel sure, meet with the approval of those who remember the peculiar circumstances of the case. In a scuffle, following upon the ejection of a drunken man from his surgery on his refusal to leave, the man sustained a fracture of the skull. This was not suspected at the time, and he was left in his clothes and untended for six days at his home before being removed to the hospital. Moreover, at the autopsy he was found to have been suffering from extensive renal and cardiac disease. Mr. Ayres might well plead that the catastrophe was of the nature of a misadventure, and although the jury declined to endorse that view, it evidently commended itself to the Council.

International Amenities and the Mount Vernon Hospital.

While politics engender jealousy and commerce breeds rivalry between the nations of the earth, science has done much to lessen racial prejudices, and the beneficial influence of co-operation is nowhere more marked than in matters concerning the health of humanity. As evidence of the good feeling existing between British physicians and German scientists, we welcome the recent graceful act of Professor Koch, the "discoverer of the tubercle bacillus," who has presented to the library of the Central Out-patients' Department of the Mount Vernon Hospital an excellent portrait of himself. This is a pleasing testimony to the excellent work of one of our most progressive British institutions. We are pleased to find that the King's Hospital Fund has made a grant of £1,000 to support fifteen beds in the hospital at Hampstead in addition to a donation of £500. We learn also that the erection of the country branch at Northwood, which will accommodate at least an additional 100 patients, is advancing rapidly. New offices and a commodious and fully-equipped out-patients' department is being prepared in Fitzroy Square, and considerable extensions at the hospital are now in progress. The Mount Vernon Hospital is rapidly taking its place among our leading national establishments for the treatment of consumption, and very shortly at least 240 beds will be available. It is well to remember that the recent extension of the hospital has been rendered possible by the munificence of a benefactor, who, however, still desires to remain anonymous.

Taxis in Strangulated Hernia.

Many surgeons are strongly averse to the employment of taxis for the purpose of endeavouring to bring about reduction of a strangulated hernia, on the ground that it is often fraught with very disastrous consequences. Obviously the employment of too prolonged or too violent force is attended with considerable risk of bringing about reduction *en masse*, but that this rarely follows resort thereto in skilled hands is proved by reference to hospital reports, which prove that this complication is of the rarest possible occurrence in hospital, where, of course, taxis is applied only by those who realise what degree of force is admissible. To do away altogether with taxis in these cases would unquestionably add greatly to the already grave risks associated with this condition. Only the failure of moderate taxis can determine the absolute necessity for operation, and the mortality following operation is far too high for it to be the intervention of selection. It simply amounts to this, that taxis applied to hernia, strangulated or otherwise, is a procedure calling for the exercise of gentleness and prudence, bearing in mind that in cases where no omentum is present in the sac to act as a buffer, a comparatively slight amount of manipulation may gravely injure the delicate bowel.

The Pathology of Gonorrhœal Rheumatism.

The occasional association of arthritis with an attack of gonorrhœa has given rise to much inconclusive discussion as to the exact relationship of the two. Inasmuch as this complication occurs especially in individuals of rheumatic antecedents, it has been asserted to be merely of the nature of a coincidence. That this should be the case appears in the highest degree improbable. Its occurrence is too frequent to be merely a coincidence, and no valid reason is advanced why the arthritic tendency, if of the ordinary type, should localise itself, as is generally done in this connection, in only one large joint, usually the knee. Moreover, the other symptoms associated with articular rheumatism are wanting. Recent bacteriological researches conclusively prove the direct dependence of the joint affection on the urethral infection. In an instructive case reported by Dr. Vaquez, two sisters, who contracted gonorrhœa from the same individual, both developed monoarthritis, and, although the synovial fluid apparently did not contain gonococci, numerous colonies of the organism were discovered in the synovial granulations, proving the specific nature of the lesion. The fact that both sisters were similarly affected supports the view that the soil is not without importance in determining the liability to arthritis as a complication of gonorrhœa. In another case the husband and wife while suffering from gonorrhœa both developed arthritis, a fact which may be interpreted in favour of the view that the specific virulence of the gonococcus has more to do with the production of arthritic complication than the soil, since in all these cases the same organism determined the arthritic lesions in different subjects. The important point, however, is the specific nature of the arthritis which may be regarded as established.

Cosmetic Injections of Paraffin.

The injection of paraffin for the purpose of remedying facial and other deformities bids fair to become a recognised and popular procedure. Much experience has already been accumulated in favour of its efficacy and innocuousness, although there has not been complete immunity from undesirable, and even disastrous, results. Exceptionally, the injection has given rise to violent local reaction, followed by sloughing of the integument, but this untoward result may be attributed to the injection of too large a quantity of paraffin, especially when the skin is adherent or adjacent to bone. In one case some of the paraffin seems to have entered the circulation, causing unilateral amaurosis, due presumably to its setting up embolism of the ophthalmic vein. This mishap, which would constitute a serious drawback were it of frequent occurrence, may be avoided by making the injection just when the paraffin is on the point of solidification, thus obviating the risk of its entrance into a wounded vein. Caution is advisable when the skin over the area to be injected is tense, adherent, or unprovided with a fair amount of subcutaneous tissue. What happens to the paraffin in the long run is a point as yet undecided, and it is not perhaps one of immediate importance. By the judicious use of paraffin injections we have at our disposal a means of remedying disfigurements which are the source of considerable distress to the victims, and in certain cases it is also of service in restoring the mechanical function of parts after loss of tissue.

Why do Digestive Organs not Digest Themselves?

Physiologists have laboured long, and not with conspicuous success, to explain how it is that digestive juices do not act on the glandular tissues by which they are secreted. Numerous hypotheses have been advanced, but none of them can be regarded as altogether satisfactory. A possible explanation may be that they do digest the secretion-producing cells. We know that the wear and tear of secretory cells is proportionate to the activity of the gland, and the persistence of the gland as a whole may be due simply to the automatic evolution of fresh cells to take the place of those which have perished by reason of their contact with the digestive secretion. The suggestion that such secretions are only poured forth when there is food to be acted upon, and that in the absence of the latter the glands are inactive, is not based on scientific data, since the food does not enter the ramifications of the glands and cannot protect the duct walls against their action. In the case of the stomach, the alkaline reaction of the tissues may conceivably prevent the action of the gastric juice on the walls, but this argument does not apply to the pancreas, the ferments whereof do not require an acid medium to produce their characteristic effects. The problem is complicated by the fact that in certain morbid conditions the gastric juice does act on the epithelial lining of the stomach walls, but this may be due to some local defect of resistance, such as would be entailed by interference with the blood supply to the part. No explanation other than the assumption of an essential power of resistance, which is the property of living tissues, adequately explains their immunity, and we have an analogous phenomenon in the fact that living tissues in some way inhibit the coagulation of blood, or at any rate induce it much less readily than do dead ones.

The Opening of the New Medical Institute in Belfast.

The principal medical event of the past week, so far as Ireland is concerned, was the formal handing over to the Ulster Medical Society of the Medical Institute which has been so generously presented by Sir William Whitla to the medical profession in Ulster. His Excellency the Lord Lieutenant, who was a visitor to Belfast during the past week, graciously consented to attend the opening ceremony, and to perform the pleasant duty of declaring the Institute open. His Excellency, in the course of his speech, bore testimony to the generous and self-depreciatory spirit in which Sir William Whitla had made his gift. "It is not everybody who realises that merely giving people something, unless it is done in a tactful way, does not always meet with the thanks that the giver expects. Now, I know that Sir William Whitla, in presenting you with this building, has done so in the most tactful and the most unadvertising manner possible." We are sure that his Excellency's words were echoed by the members of the medical profession present. We congratulate the Ulster Medical Society on the receipt of so valuable a gift, and re-echo his Excellency's hope "that its roll may contain for many years the names of many distinguished Irish doctors." We are pleased to be able to present to our readers a full report, which was specially obtained for our columns, of the opening ceremony, and also to reproduce an illustration of the Smyth memorial window. We are the more pleased to publish this, inasmuch as in certain quarters there appears to be a desire to decry the importance of the new Institute, and the proceedings of the past week in general.

THE death is announced from appendicitis of Dr. Walter Reed, of the United States Army Medical Service, to whose investigations into the etiology of yellow fever while stationed at Havana we owe much useful information concerning the transmission and the means of checking the spread of the disease.

DR. MALONE LEE, A.B., M.B., B.Ch., B.A.O., R.U.I., has been elected senior house physician at the Mater Misericordiæ Hospital, Dublin.

A PORTRAIT of Dr. Professor Robert Koch has been placed in the library of the Mount Vernon Hospital for Consumption, having been "presented by request" of the eminent professor.

SIR MICHAEL FOSTER, M.P. for the University of London, announces his intention of resigning at the close of the present session. Sir John Williams and Sir Henry Roscoe are mentioned as probable candidates for the representation of the University.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

"FANATICS AND THE PUBLIC HEALTH."

To the Editor of THE MEDICAL PRESS AND CIRCULAR

SIR,—As a member of the International Congress for the Prophylaxy of Venereal Diseases, recently held in Brussels, will you kindly allow me to point out that there is not the slightest ground for supposing that the regulation system abroad, or the Contagious Diseases Acts (Women) in this country, have either, or both of them ever had any beneficial influence upon the incidence of venereal diseases either in this country or elsewhere. Indeed it goes without saying that a sanitary law applicable to one sex only must necessarily fail to attain the end in view, for men (soldiers, sailors, explorers, the mercantile marine, and others) are undoubtedly the most active propagators of syphilis all over the world, and so long as they are untouched and free to spread disease it is idle to expect any so-called stamping-out by dealing with women only. Besides, clandestine prostitution, the natural and inevitable outcome of the system, always has wrecked and always will wreck any attempt to deal with disease in this fashion, for it is well known that do what you may, only one in ten, or one in twenty of the women who are now and then sources of infection can be got on to the register of infamy at all, while those who escape registration, for fear of their natural enemies the police (who, it is well known commit the most shameful outrages), conceal their diseases, and are consequently never properly treated and become more dangerous than ever. Even those on the register cannot be forced to attend regularly or often enough. The menstrual period precludes examination in a vast number of cases. We cannot distinguish gonorrhœa from leucorrhœa (which latter is so common among all classes of women that high authorities have declared it to be a normal condition). We cannot detect a discharge if it has been washed away, and we cannot say whether such discharge, even if detected, would communicate gonorrhœa or syphilis (if the patient has previously had syphilis, though no signs of it are present), or whether, as is so often the case, it would prove to be quite innocuous. Everyone of experience knows that it is only very rarely and with great difficulty that we can detect the initial lesion of true syphilis in the female, a detection not likely to be made in the perfunctory examinations of women by the score or hundred, and unquestionably there is great risk of spreading disease to healthy women by unclean instruments. Clearly such a system, by the false security which it gives, can only aggravate every evil, both physical and moral. It has done so and always will do so. The resolution proposed by Dr. Landouzy, the well-known and distinguished physician of Paris (at the Brussels Congress), declared, "That the regulation system as it exists has proved ineffectual and ought to be abandoned." He was backed by Professor Gailleton, Professor Gaucher, Dr. Queyrat, Dr. Fiaux, Dr. Sicard de Plauzolles (France). Dr. Santoliquido (Italy), Dr. Blaschko (Germany), Dr. Ernest Lane (England), Dr. Morgenstierne, Dr. Boeck (Norway), Dr. Rethaari Macaré (Holland), and numerous others. Ricordi used to say, "That if a man wishes to escape syphilis he must avoid the risk of catching it ; there is no other way."

I am, Sir, yours truly,

M. D.

Literature.

HAMER ON PUBLIC HYGIENE. (a)

THIS handsomely got-up and well-written volume deals in a masterly manner with the varied problems of the very important science whose theory and practice it undertakes to teach. The contents are divided into twelve chapters, of which the first is "Introductory," and deals with "The Rise and Progress of Preventive Medicine," and a most interesting and instructive document it is; the second deals with the all-important subject of "Air"; the third with that of "Water"; the fourth with that of "Soil"; the fifth with the engrossing subject of "Food"; the sixth bears the title, "The Collection, Removal, and Disposal of Refuse"; the seventh, "Dwellings, Schools, and Hospitals"; the eighth, "Parasites—Infection—Immunity"; the ninth, "Infectious Diseases"; the tenth, "Disinfection"; the eleventh, "Vital Statistics"; and the twelfth, "Sanitary Administration and Sanitary Law."

This text-book has been—professedly—prepared with special consideration for "the needs of those who are seeking a Public Health Diploma." We can congratulate the author on the effectiveness with which he has carried out his self-imposed task. So far as we know there is no better guide-book at present existing in the English language for the student who is about to investigate the mysteries of the dark places of the engrossingly important subject of preventive medicine. From "the first great landmark of epidemiology," which is to be found in the "Epidemics of Hippocrates," to the most recent illuminations of bacteriological pathology, the author has omitted no record or discovery of any special importance for the interest or instruction of the student whom he has undertaken to teach. "The troglodyte flint-chipper may have suffered from what is known as 'silicosis,'" and the legislation of the closing years of the nineteenth century has taken precautions "for securing the cleanliness of milk stores, milk shops, and milk vessels; for prescribing precautions to be taken for protecting milk against infection or contamination." Every intermediate stage in the long succession of centuries which has contributed anything worthy of survival to the formulation of the laws necessary to the preservation of the general health of the human race, has received a due proportion of attention, within the writer's prescribed limits. The subjects of malaria and tuberculosis may safely be taken as tests of the trustworthiness of the up-to-date information supplied by this manual; and we can unhesitatingly say that we cannot find a flaw in its teaching. After this announcement we need only close this notice by recommending the volume to all students of hygiene, and wishing its future all the success which it thoroughly deserves.

(a) "Manual of Hygiene." By W. H. Hamer, M.A., M.D., D.P.H.Cantab., B.Sc.Lond., F.R.C.P., Lecturer on Public Health, St. Bartholomew's Hospital. With 93 Illustrations. 8vo. Pp. xii and 622. Price 12s. 6d. net. London: J. and A. Churchill. 1902.

SAVILL ON NEURASTHENIA. (*a*)

During the last quarter of a century much has been done in the generalisation of knowledge of the obscure depreciation of the nervous system which is known as neurasthenia. This morbid state, so protean in its manifestations and so vague in its clinical delimitations, has so far gained in public esteem that we are confronted with the danger of its being made, like muscular rheumatism and influenza, a cloak for ignorance or diagnostic incapacity.

The subject is one which has a copious literature, and it cannot truthfully be affirmed that many additions to the list of contributions thereon add in any tangible degree to our knowledge of the subject. For the present, however, it is of much greater importance to impart what may be called a working knowledge of the subject to practitioners than to seek to trace its more recondite manifestations and phenomena. This is especially the case in view of the very satisfactory results afforded by treatment thoroughly carried out on scientific lines.

In these lectures the very important subject of etiology is carefully discussed at considerable length. That is well, because success in treatment depends very largely on a proper comprehension of the factors in the individual case. If we do not remove the cause, we cannot reasonably expect to obviate the effects. True, the multiplicity of factors which tend, singly and collectively, to bring about the nervous deterioration which is the anatomical basis of the disease, may appear bewildering to the student, but it will widen his point of view and assist him in grasping the clinical significance of the particular manifestations with which he is confronted.

The author has adopted the only trustworthy plan of dealing with the subject, viz., by relating judiciously selected cases. Thanks to a good literary style, the author has succeeded in investing his theme with interest, and although he does not pretend to have exhausted the subject, he has said enough to convey a comprehensive and fairly adequate idea of this complex morbid state.

ABDOMINAL EXAMINATION. (*b*)

Considering the ease with which, in women of ordinary build, the position of the fœtus *in utero* can be made out by abdominal palpation, and the number of years that the procedure has been taught at the Continental schools of obstetrics, it is difficult to resist a feeling of surprise, with a twinge of humiliation, at its introduction, by the author, as "a subject which receives, as a rule, only passing attention." Even Professor Murdoch Cameron, in his introduction, commends the author for having "abstained from pressing crude ideas into notice," as though the method had not years since been carefully worked out to a practical conclusion by Pinard, of Paris, and others.

The fact is that Great Britain possesses no real school of obstetrics, and students are left in great measure to pick up their practical knowledge as best they may. Otherwise no student would be admitted to the profession without a good working knowledge of the abdominal method of obstetrical diagnosis.

In spite of the fact that attention has over and over again been called to the practical utility of this method, it is dealt with, if at all, only in a perfunctory manner in the popular text-books and—a far more important point—the student is only exceptionally instructed in its application. It remained for the author to write the first work in the English language on the subject, and we urgently commend it to the careful attention of students and practitioners.

Of course it is not proposed that the external or abdominal method shall take the place of vaginal examination, although, as a matter of fact, the information it yields is, as a rule, far more conclusive than the latter. Still, it has its limitations, and the author, in our opinion, goes a good deal beyond its strictly legitimate application. Better too much than too little, however. We would only suggest that it would not be difficult to provide better illustrations than the blotchy photogravures which are all he supplies in the present edition.

TURNER'S MANUAL OF ELECTRICITY. (*a*)

The appearance of a third edition of this book is a sufficient warrant of its excellence. The aim of the author has evidently been to produce a practical work on the subject, a purpose for which he is eminently fitted by a long experience as a teacher and examiner in the Edinburgh University. The body of the book is occupied by a clear description of the electrical principles, the apparatus, and the special methods involved in medical electricity. There is no need to enter into any detailed criticism of a well-known book of this kind in its third edition. At the same time it may be said generally that the medical man who takes the trouble to master the contents of this volume will be in a position to appreciate at its proper value the art of electro-therapeutics. The importance of the subject is growing daily with the rapid extension of scientific knowledge of the facts relating to the physics, the physiological action and the therapeutics of electricity. Under the section dealing with the reactions of nerves and muscles we miss any mention of the classical researches of Duchenne and Von Ziemssen. The section upon electro-therapeutics is valuable and up-to-date. A similar remark may be made of the chapters on the Röntgen rays, which give a capitally condensed account of principles, methods, and applications. We notice, by the way, that the author falls into the curious error of stating that the Jackson focus-tube was introduced after the announcement of Professor Röntgen's discovery. As a matter of fact it was in existence for a considerable time before 1896. Some of the author's illustrations are interesting and one or two show excellently what good work was obtained even in the early stages of investigation. The author's illustrations of the Dunfermline shooting case, in which he demonstrated by oblique irradiation the presence of a bullet buried near the spine, recalls an early observation which at the time had considerable suggestive and original value. Dr. Turner's book may be confidently recommended to all who are in want of a handbook in this particular province of medicine.

INTERNATIONAL CLINICS. (*b*)

The difficulty of giving a reader a true picture of the wealth of information one of these volumes contains is very great. Every branch of medicine is dealt with:—Therapeutics, medicine, surgery, obstetrics, gynæcology, and in a series of special articles the organisation of the Medical Department of the U.S.A. Army is dealt with by Dr. Manson, whose great work, "Military Hygiene," finds a place in every good library. Dr. Kelly writes of the management of a modern private hospital, and Dr. Borissoff recounts the original work on digestion, and tells of the wonderful experiments that Professor Pavlof, of St. Petersburg, has been carrying out. We think the publication is one well deserving of the support of the members of the medical profession,

(*a*) "Manual of Medical Electricity." By Dawson Turner, B.A., M.D., M.R.C.P., &c., Lecturer in Experimental Physics, Surgeons' Hall, Edinburgh; Examiner Edinburgh University; in charge of Electrical Department, Edinburgh Royal Infirmary, &c. Third Edition. 12s. 6d. London: Bailliere, Tindall and Cox.

(*b*) "International Clinics. A Quarterly of Illustrated Clinical Lectures and specially prepared articles." By Leading Members of the Medical Profession throughout the World. Edited by Henry W. Cattell, A.M., M.D., Philadelphia. Volume II. Twelfth Series. 1902. London: J. B. Lippincott Co.

both from the intrinsic value of the articles and their practical character. Each volume is complete in itself, and we look on them as among our most valued books. But we think that the editor would have been well advised to have left out the "selected prescriptions"—readers of the "International Clinics" do not require such. And we cannot say that we admire the biographical sketch. We care not what are the hours of sleeping and eating of a medical celebrity. On page 226 we find the Cheselden operation called the Chesterton, an obvious typographical error, but one that is to be regretted in a high-class periodical. We have told all that we disapprove of, but space does not admit of our telling of all the excellent and original articles it contains, both suggestive and helpful.

CLINICAL METHODS. (*a*)

This second edition has been materially revised and some important additions have been made. The authors, however, were well advised in not attempting to bring a work of this kind too abreast of the times, in view of the difficulty which exists in deciding forthwith what of the new is good and is likely to be durable.

The author disclaims any intention to write a treatise on medical diagnosis, but since this work aims at describing the methods of clinical investigation by which a correct diagnosis can alone be arrived at, it is not easy to differentiate.

The plan adopted is to select a particular organ or system and to go, stage by stage, over the various points to be observed in connection therewith, indicating the conclusions to be drawn from special signs and appearances. That is done in the briefest possible manner consistent with lucidity, and the text is elucidated by upwards of 150 illustrations and eight coloured plates.

This compact little book, of convenient size and solidly bound in the familiar red covers, may be trusted to impart a working knowledge of this very important branch of medical study. It is in reality an amplification of the Hippocratian maxim that medicine consists wholly of observation.

PHYSICAL DIAGNOSIS. (*b*)

The science of close and accurate observation is so intimately related to medicine, so indispensable to progress for a student, and to success for a practitioner, that its acquisition must be desired by all. It is, of course, embodied in the ordinary text-books, since it is the foundation of diagnosis, but it is well that so fundamental a science, in reality a "frame of mind," should be viewed apart, and made the subject of special study.

The shortcomings of previous editions have been remedied in this, the third edition, in the light of experience, and the author has added, among others, chapters on the examination of the blood, on the cranial nerves, and on clinical bacteriology which brings this otherwise excellent treatise up to date. The number of illustrations has also been materially increased.

As a guide to the physical examination of the sick we know of none to surpass this popular manual. The text is lucid and free from redundancies. It can be cordially recommended to the student desirous of becoming proficient in the elements of diagnosis.

OUTLINES OF PRACTICAL PHYSIOLOGY. (*c*)

This edition, dedicated to the celebrated French physiologist, M. Charles Richet, has been revised and enlarged, the additions bearing more especially on the experimental part, free use having been made of all the works on practical physiology published since the last edition. Under title of "The Physiology of the Senses" the subject of physiological psychology has been adequately dealt with—adequately, that is to say, from the students' point of view.

The illustrations, which number upwards of 460, consist largely of the various apparatus made use of in experimental physiology and of diagrams of the results obtained therewith.

The work is essentially a practical one. Its object is to enable the student to master the steps by the aid of which the details of the physiological processes are worked out. Even when it may be thought unnecessary to repeat the experiments, it is none the less necessary to grasp the nature of the data upon which the conclusions have been arrived at.

The body of the work defies detailed criticism. We can only say that it bears evidence on every page of conscientious work and careful scrutiny of current work. The volume is already too well known to need further commendation at our hands.

NEW BOOKS AND NEW EDITIONS.

The following have been received since the publication of our last list:—

Felix Alcan (Paris).

Les Obsessions et la Psychasthenie. By Dr. Pierre Janet. Pp. 764. Price 18 francs.

Les Nouveaux Traitements. By Dr. J. Laumonier. Pp. 280. Price 4 francs.

J. B. Bailliere et Fils (Paris).

La Profession Médicale. By Paul Brouardel. Pp. 228. Price 3fr.50.

Bailliere, Tindall and Cox (London).

Selected Papers on Operative and Clinical Surgery. By the late William Stokes, M.D. Edited by William Taylor, B.A., M.B., with memoir of author by A. Ogston, M.D. Pp. 484. Price 10s., net.

J. and A. Churchill (London).

Malarial Fevers of British Malaya. By Hamilton Wright, M.D. McGill. Pp. 98. Price 3s., net.

J. B. Lippincott Co. (London).

Internatonal Clinics. Vol. III. Edited by Henry W. Chattell, M.A., M.D. Philadelphia. Pp. 306. Price 10s. 6d.

Longmans, Green and Co. (London).

The Morals of Suicide. By Rev. J. Gurnhill, B.A. Vol. II. Pp. 220. Price 5s. net.

Transactions of the Clinical Society of London. Vol. 35. Pp. 235.

M'Corquodale and Co., Ltd. (London).

Metropolitan Asylums Board. Annual Report, 1901. In two vols. Price 5s.

Young J. Pentland (Edinburgh and London).

Manual of Bacteriology. By Robert Muir, M.A., M.D., F.R.C.P. Ed., and James Ritchie, M.A., M.D., B.Sc. Third Edition, with 150 illustrations. Pp. 548.

W. B. Saunders and Co. (Philadelphia and London).

The Elements of Bacteriological Technique. By J. W. H. Eyre, M.D., M.S., F.R.S.Ed. With 170 illustrations. Pp. 371.

Diseases of the Pancreas and their Surgical Treatment. By A. W. Mayo Robson F.R.C.S., and B. G. A. Moynihan, M.S. Lond., F.R.C.S. Illustrated. Pp. 293.

Sherratt and Hughes (Manchester).

The Pharmacological Action and Therapeutic Uses of the Nitrates and Allied Compounds, including the Croonian Lectures for 1893. By the late Daniel John Leech, M.D. Lond., D.Sc. Vict. F.R.C.P. Edited by R. B. Wild, M.D. Lond., &c. Pp. 187.

University Press (Liverpool) and Longmans, Green and Co. (London).

Second Progress Report of the Campaign against Mosquitoes in Sierra Leone. By M. Logan Taylor, M.B., Ch.B. Pp. 13. Price 1s.

Report on the Sanitary Conditions of Cape Coast Town. By M. Logan Taylor, M.B., Ch.B. Pp. 19. Price 1s.

Williams and Norgate (London).

Cancers and other Tumours of the Breast. By Charles Creighton, M.D. With 24 lithographic plates. Pp. 296. Price 20s. net.

Medical News.

Irish Medical Schools' and Graduates' Association.

A complimentary dinner to Lord Roberts was given by the members of this Association in the Great Hall of the Hotel Cecil on Wednesday last, when an unprecedented number of members and their lady friends joined in the gastronomic fray. The chair was occupied

---

(*a*) "Clinical Methods." By Robert Hutchison, M.D., M.R.C.P., Assistant Physician to the London Hospital, &c.; and Harry Rainy, M.A., F.R.C.P.Ed., F.R.S.E., Univ. Tutor in Clinical Medicine, Royal Infirmary, Edinburgh. Price 10s. 6d. London: Cassell and Co., Limited. 1902.

(*b*) "Gibson and Russell's Physical Diagnosis." Third Edition, Revised and Rewritten, by Francis D. Boyd. C.M.G., M.D., F.R.C.P.Ed., Assistant Physician, Edinburgh Royal Infirmary. Edinburgh: Young J. Pentland. 1902.

(*c*) "Outlines of Practical Physiology." By William Stirling, M.D., D.Sc., Brackenbury Professor of Physiology and Histology in the Owens College, and Professor in Victoria University, Manchester. Fourth Edition. Price 15s. net. London: Charles Griffin, Ltd. 1902.

by Sir Philip Smyly, the president, and among those present were Lady Aileen Roberts, Sir P. Hutchins, Sir William Turner, president of the General Medical Council, Sir William Thomson, Mr. Justice Wills, Sir James Crichton Browne, Lord Headley, Lieut.-Colonel W. Babtie. The event of the evening was the presentation to Captain Crean, V.C, R.A.M.C., of the Arnott Medal founded in 1900, for award by the Council for an act of heroism or distinguished service in civil life or in the services. The medal, which was described by the president as the professional Victoria Cross, was presented by Lady Aileen Roberts, and was suitably acknowledged by Captain Crean, who looked in the best of health and spirits. In response to the toast of "Our Guests," Lord Roberts spoke in appreciative terms of the many tokens of esteem which he had received from his fellow-countrymen, and thanked the members for their kindly reception. Although not born in Ireland, he said he was of Irish descent, and it was a special pleasure to him to see before him some of the Irish medical men who went out to South Africa to help the sick and wounded, of the excellence of whose work he was gratefully cognisant. It was also a peculiar pleasure to him to see so many medical gentlemen whom he had met in South Africa—Sir William Thomson and Dr. Stoker, of the Irish Hospital, and Mr. O'Callaghan, of the Langman Hospital, and he knew what excellent work they and many others did. He then referred to the death of Sir William Stokes, who had lost his life in South Africa, where doubtless Sir William McCormac had also laid the seeds of his fatal disease. The proceedings throughout were of the most enthusiastic character, and every credit is due to Dr. J. H. Swanton, the honorary secretary, for the eminently satisfactory way in which the organisation of this huge gathering was carried through.

A Sale of Practice Dispute.

An action was tried in the Nisi Prius Court, at Liverpool, last week, in which Mr. Thomas Godley, L.R.C.P., L.R.C.S.Edin., now of Blackpool, sought to recover the balance of the purchase money of his practice at Bolton from Mr. Robert Harding Rains, M.R.C.S. The defendant, on the other hand, claimed damages for fraudulent misrepresentation. The practice, which was stated to have brought in about £800 a year, was mainly of the sixpenny class. The defendant appeared to have been afforded every opportunity of ascertaining the nature of the practice before concluding the purchase, and the jury ultimately gave a verdict in favour of the plaintiff for the amount claimed.

Chloroform Catastrophe.

Mr. Turberville Buckle, M.B.Lond., L.R.C.P., M.R.C.S., of Vicarage Villas, Willesden, was found dead in his bed one morning last week. He was holding a handkerchief to his mouth, and at the bedside was a partially emptied bottle of chloroform. It is surmised that in the endeavour to procure sleep he inadvertently inhaled an overdose. At the inquest a verdict of death from misadventure was returned.

Central Midwives Board.

Privy Council Office, Nov. 25th, 1902.

In pursuance of Section 3 of the Midwives Act, 1902, the Central Midwives Board has been constituted as follows:—

Names of Members.	Appointed by
W. J. Sinclair, Esq., M.D. Miss Jane Wilson	Lord President of the Council.
F. H. Champneys, Esq., M.D....	Royal College of Physicians
J. W. Cousins, Esq., F.R.C.S.	Royal College of Surgeons.
E. P. Young, Esq., M.R.C.S., L.S.A.	Society of Apothecaries.
Charles J. Cullingworth, Esq., M.D., F.R.C.P. ...	Incorporated Midwives' Institute.
J. H. Johnstone, Esq., M.P.	Association of County Councils.
Miss Rosalind Paget... ...	Queen Victoria's Jubilee Institute for Nurses.
Miss Dorothea Oldham ...	Royal British Nurses' Association.

Deaths Under Chloroform.

A lad, aged 15, died at the General Hospital, Birmingham, under chloroform, administered for the removal of adenoids. A post-mortem examination has been ordered to determine whether death was due to the anæsthetic or to the passage of blood into the larynx. We have often insisted on the undesirability of employing such an anæsthetic as chloroform for this trivial operation, since nitrous oxide amply suffices; indeed, it is hardly necessary in most cases to induce anæsthesia at all. At an inquest held on the body of a girl, aged 12, who had died under chloroform at the Westminster Hospital, it was stated that the heart continued to beat eight hours after breathing had ceased, and death was attributed to paralysis of the centre of respiration due to chloroform.

Nobel Prize Award.

Three of the Nobel prizes have this year been awarded as follows: Medicine and Physiology: Dr. Finsen, the Danish physician whose method of curing lupus, &c., by exposure to light has been so successful. Chemistry: Dr. Emil Fischer, of Berlin, one of the world's leading chemists. He is fifty-one years of age, and has devoted himself principally to organic chemistry, with particular reference to the constitution of sugar stuffs. Physics: Dr. Orrhenius, of the Stockholm High School.

An Anti-Sanatorium Action.

The tenant for life of a large settled estate at Bexhill-on-Sea has brought an action against Dr. Wills to prevent him carrying on a private hospital for chest complaints at Marine Mansions in such a way as to be a nuisance. It appears that the house has been converted into an establishment for the open-air treatment of consumptives, for whose benefit the windows have been taken out and the balconies placed at their disposal for day and night use. The front of the house is brilliantly lighted by electricity and attracts considerable attention. Judgment has not yet been delivered.

Carbolic Acid to be Scheduled.

The Departmental Committee on Poisons, it is reported, are prepared to recommend the inclusion of carbolic acid in Schedule 3 of the Pharmacy Act. This anticipation, if realised, will accomplish a much-needed reform, and may do something to lessen the appalling number of deaths from the ingestion of this poison, by accident or otherwise.

Death under Ether.

A man, aged 41, who was about to undergo an exploratory operation at St. Bartholomew's Hospital for a growth in the neck pressing on the trachea, was anæsthetised by means of gas and ether, but six minutes after anæsthetisation was commenced the breathing became embarrassed. Although tracheotomy was at once performed, he died. The tumour in question weighed upwards of twenty ounces, and, it is stated, would in any event soon have caused death.

Dublin Death-Rate.

The deaths registered in the Dublin registration area for the week ending Saturday, November 22nd, 1902, represent an annual death-rate of 32·6 in every 1,000 of the population. There were 32 deaths from tuberculous disease; 32 from disease of the nervous system; 52 from diseases of the respiratory system; and 23 deaths from diseases of the circulatory system; 119 infants died during the week, of whom 68 were under one year old. In the City dispensary districts the death-rate was as follows:— Lisburn Street District, 41·6 per 1,000; Blackhall Place District, 46·1 per 1,000; Castle Street District, 39·6 per 1,000; and in Peter Street District, 47·8 per 1,000.

Trinity College, Dublin.—Michaelmas, 1902.

Final Examination in Medicine.—Anthony H. Corley, Demetrius Jacovides, Henry T. Brady, Thomas W. Crowley, William I. de C. Wheeler, Arthur A. Burrell, Bertram L. Middleton, John H Torney, Charles A. Stone, William Leggett, John H. Askins, Edward V. Cullen, Nicholas M. Cummins, Joseph Wallace. M.B. Degree.—Henry A. Hanan.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

IN the Pass List which we published last week the name of Miss May Thorne was erroneously given as Miss Thom.

M.R.C.S., L.R.C.P.Lond.—The consultant's action was, perhaps scarcely courteous, but it does not appear to constitute a breach of the well-defined ethical rule applying to such cases.

DR. LE SAGE.—To have been explicit, under the circumstances, was the only course which you could adopt. The fact that the patient made use of the information is a regrettable incident in the affair, but nevertheless one which, in the end, is likely to prove beneficial to our correspondent.

AN ANCIENT STORY.

A FEW years ago, at the presentation of the prizes of the Medical School at University College, Dr. Lyon Playfair being present, Mr. G. Shaw-Lefevre, M.P., told the following story:—"In 1739 a quack, named James Steven, professed to have discovered a medicine for curing a painful disease, and he puffed it so successfully that Parliament passed an Act awarding him £5,000 on condition that he would inform a Royal Commission of the nature of his remedy. The Royal Commission consisted of an archbishop, ten bishops, the Lord Chancellor, three Ministers of State, five peers, and ten men of science. In due time the Royal Commissioners reported that they had examined the remedy and found it to be of great utility and benefit. The £5,000 was awarded to Mr. Steven. The reputed remedies consisted of three items - a powder, a pill, and a decoction. The powder was a mixture of pulverised egg-shells and snail-shells: the pill was composed of egg-shells, soap, and honey; while the decoction was made up of soap and a substance called 'swines' cresses.'"

Meetings of the Societies, &c.

LONDON.

WEDNESDAY, DECEMBER 3RD.

OBSTETRICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. Blacker, Dr. Giles, Dr. Lewers, Dr. W. C. Swayne, Dr. Sikes, and Mr. Malcolm. Short Communication:—Dr. V. Bonney: Dermoid Cyst containing a large number of Epithelial Balls. Paper:—Dr. G. E. Herman and Dr. H. R. Andrews: A Contribution to the Natural History of Dysmenorrhœa.

THURSDAY, DECEMBER 4TH.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Discussion on the Surgery of Acute Appendicitis; opened by Mr. C. B. Lockwood.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 p.m. Clinical Cases.

RONTGEN SOCIETY (20, Hanover Square, W.).—8.30 p.m. Mr. Isenthal will show the Nodon Electic Valve for Converting Alternating into Continuous Current. Dr D. Walsh: An Observation bearing upon the Therapeutic Action of the Focus Tube. Paper:—Mr. S. Mayou: X-Rays in Ophthalmic Work (with lantern slides).

NEUROLOGICAL SOCIETY OF LONDON (Physiological Laboratory, University College).—8.30 p.m. Meeting.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—5.30 p.m. Mr. Berry: Diseases of the Thyroid.

FRIDAY, DECEMBER 5TH.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich Road, S.E.).—8.45 p.m. Mr. A. Bowlby: The Simulation of Intestinal Obstruction (Purvis Oration). Conversazione. Demonstrations:—The President and Mr. L. Eastes: Some Clinical Tests and Scientific Methods of Cultivation of Bacteria. Mr. J. J. Vezey: X-Ray, High Frequency Electrical, and Vibro-Therapeutical Apparatus, and Finsen Lamps. Messrs. Arnold and Son will exhibit Surgical Instruments.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover Square, W.).—5 p.m. Cases Specimens, and Instruments will be shown by Dr. L. Turner, Mr. W. R. H. Stewart, Mr. A. H. Burt, Dr. S. Spicer, Mr. F. J. Steward, and others.

TUESDAY, DECEMBER 9TH.

WESTMINSTER HOSPITAL (Broad Sanctuary, S.W.).—4.30 p.m. Mr. Paton: Surgical Cases. (Post-Graduate Clinical Demonstration.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—5.30 p.m. Mr. Tubby: Injuries to the Spine.

THURSDAY, DECEMBER 11TH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos Street, W.).—Clinical evening. Cases, &c., by Messrs. Mayou, Edridge-Green, Charles Blair, Bernard Potter, Ernest Maddox, Sydney Stephenson, N. C. Ridley, and E. T. Collins.

FRIDAY, DECEMBER 12TH.

THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11, Chandos Street, W.).—5 p.m. Special Meeting for the Discussion of Tuberculous Peritonitis.

DUBLIN.

FRIDAY, DECEMBER 5TH.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Pathological Section:—Dr. H. Collett and Professor O'Sullivan: Cancer of Ovary. Dr. Earl: Sarcoma of Suprarenal Capsule. Drs. Maunsell and Earl: Carcinoma of Transverse Colon. Dr. Earl: Obstruction of Cystic Duct. Dr. Benson: Intra-ocular Tumour.

Appointments.

GORDON, WILLIAM, M.D.Cantab., Physician to the West of England Eye Infirmary.

HARSANT, WILLIAM HENRY, F.R.C.S.Eng., Honorary Consulting Surgeon to the Bristol Royal Infirmary.

LYSTER, C. R. C., M.R.C.S., Medical Officer to the Finsen Light and X-ray Department at the Middlesex Hospital.

MOLE, HAROLD F., F.R.C.S.Eng., Surgeon in charge of the Ear Department, Bristol Royal Infirmary.

MORGAN, D. J., M.B., B.C.Cantab., Pathologist at the Cancer Hospital, Fulham Road.

PICKARD, RANSOM, M.D., M.S.Lond., F.R.C.S.Eng., L.R.C.P.Lond., D.P.H.Cantab., Honorary Assistant Surgeon to the West of England Eye Infirmary, Exeter.

ROPER, ARTHUR CHARLES, F.R.C.S., L.R.C.P.Edin., M.R.C.S.Eng., Honorary Surgeon to the West of England Eye Infirmary, Exeter.

SHERREN, JAMES, F.R.C.S.,Eng., Assistant Demonstrator of Anatomy at the London Hospital Medical College.

SWAIN, JAMES, M D., M.S.Lond., F.R.C.S.Eng., Honorary Surgeon to the Bristol Royal Infirmary.

SYKES, WALTER, L.R.C.P., L R.C.S.Edin., L.F.P S.Glasg., Resident Surgical Officer to the Birmingham and Midland Eye Hospital.

Vacancies.

Borough Asylum, Canterbury.—Assistant Medical Officer. Salary £120 per annum, with furnished apartments, board, and laundry. Applications to the Medical Superintendent, Borough Asylum, Canterbury.

City Asylum, Birmingham.—Assistant Medical Officer. Salary £150 per annum, with board, apartments, and washing. Applications to the Medical Superintendent.

County Asylum, Dorchester.—Second Assistant Medical Officer. Salary £140 and all found. Applications to the Medical Superintendent.

County Asylum, Whittingham, Preston, Lancashire.—Junior Assistant Medical Officer. Salary £150, with furnished apartments, board, washing, and attendance. Applications to the Medical Superintendent.

Grimsby and District Hospital.—Resident House Surgeon. Salary £100 per annum, board, lodging, and washing. Applications to J. F. Wintringham, Hon. Secretary, St. Mary's Chambers, Great Grimsby

Haydock Lodge Asylum, Lancashire.—Assistant Medical Officer. Salary £175 per annum, furnished quarters, board, washing, &c. Applications to Dr. Street, Haydock Lodge, Newton-le-Willows, Lancashire.

Hertfordshire County Asylum, Hill End, near St. Albans.—Junior Assistant Medical Officer. Salary £160 a year, with board, furnished apartments, and washing. Applications to the Medical Superintendent.

Hospital for Sick Children, Great Ormond Street, London, W.C.—Resident Medical Superintendent. Salary 100 guineas per annum, with board and residence in the hospital and £5 washing allowance. Applications to Adrian Hope, Secretary.

Manchester Royal Infirmary.—Resident Medical Officer at the Convalescent Hospital, Cheadle. £150 per annum, with board and residence. Applications to W. L. Saunder, General Superintendent and Secretary.

Rochdale Infirmary (54 Beds).—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing. Applications to the Hon. Secretary, R. W. Shaw, Esq., Southfield, Rochdale.

Southampton Incorporation.—Resident Assistant Medical Officer. Salary £100 per annum, with apartments, rations, washing, and attendance. Applications to David P. Gwillim, Clerk to the Guardians, Clerk's Offices, Workhouse, Southampton.

The Middlesex Hospital Cancer Research Laboratories.—Junior Pathological Assistant. Salary £100 per annum. Applications to F. Clare Melhado, Secretary-Superintendent.

Western General Dispensary, Marylebone Road, N.W.—Senior House Surgeon. Salary £100 a year, with board, residence, and laundry. Applications to the Hon. Secretary at the Institution.

Births.

HART-SMITH.—On Nov. 25th, at 99, Wickham Road, Brockley, S.E., the wife of Humphry Morshead Hart-Smith, M.B.,B.C.Cantab., of a daughter.

THORNE THORNE.—On Nov. 27th, at 45, Inverness Terrace, Hyde Park, W., the wife of Leslie Thorne Thorne, M.D., of a son.

WOOD.—On Nov. 28th, at Eastwood, Ferry Road, Edinburgh, the wife of Thomas Wood, J.P., M.B., C.M.Edin., of a daughter.

Marriage.

BATTLE—LLEWELLYN.—On Nov. 27th, at St. John's, Coleford, Gloucestershire, Dr. E. Wharmby Battle, 27, Hamstead Road, Handsworth, son of the late J Key Battle, of Hyde, Cheshire, and of Lincoln, to Catherine Ann Llewellyn, youngest daughter of Mrs. Buchanan, Bank House, Coleford.

Deaths.

BUCKLE.—On Nov. 27th, at Willesden, suddenly, William Turberville Buckle, M.B., aged 58.

JOHNSON.—On Nov. 25th, at Westbourne Park, London, W., Mary Susan, widow of the late F. H. Johnson, M.R.C.S., L.R.C.P., &c., of Sunderland, in her 83rd year.

LITTLE.—On Nov. 27th, at Bank House, Buglawton, Congleton, David Little, M.D., F.R.C.S., of 2, St. John Street, Manchester, and Court Heath, Buxton, aged 62.

STEPHEN.—On Nov. 28th, at 54, Evelyn Gardens, S.W., George Caldwell Stephen, M.D., L.R.C.P., D.P.H.Camb.

The Medical Press and Circular.

Original Communications.

SYPHILIS AND LIFE ASSURANCE.[a]

By **BYROM BRAMWELL, M.D., F.R.C.P., F.R.S.E.,**

Physician to the Edinburgh Royal Infirmary, &c.

The main questions to be determined were: (1) *Does syphilis tend to shorten life*, not merely in individual cases, but considering syphilitic individuals in a mass? and (2) *If so, to what extent?* Unless these questions are settled with some degree of accuracy it is impossible to give a rational and scientific answer to the question. (3) *On what terms shall assurance companies accept syphilitics?* Considering the extreme frequency of the disease it was remarkable how divergent were the views of physicians on the subject, some thinking that syphilis should in no way influence the rate of premium, and others holding a very opposite view. Most medical advisers refuse to accept cases of primary and secondary syphilis and bad cases in which tertiary symptoms have appeared, while they accept at ordinary rates cases of syphilis which have been effectively treated, and in which a sufficient time has elapsed to render the further appearance of symptoms unlikely. This practice seemed to the speaker entirely illogical on account of the possibility of later nervous symptoms developing. In his opinion syphilis shortened life, and a person who had suffered from it should not be taken as a first-class life, as it was quite impossible to foresee the risks. The only exceptions were cases in which the disease had been contracted very many years previously, or in certain cases of short-term policies. Syphilis might kill and shorten life in different ways—(1) by typical tertiary lesions, particulary those affecting the nervous system; (2) post or para-syphilitic lesions, of which tabes, general paralysis of the insane, and aneurysm were the most important, with, in addition, such other para-syphilitic manifestations as aortic regurgitation, cirrhosis of the liver, possibly cirrhosis of the kidneys, insanity, &c., and probably more subtle degenerative changes which diminish the resistance and vitality of syphilitics. Dr. Bramwell showed statistical tables of his own cases, which confirmed those published by Naunyn in showing that tabes, general paralysis and aneurysm occurred most frequently during the first ten years after infection. During this period the greatest extra premium was required, during the second decade a less one, while during the third decade very little extra might be required. At present insurance statistics were of little or no value in showing whether syphilis shortened life. In Dr. Muirhead's analysis of the mortality in the Scottish Widows' Fund from 1888·94, no death was ascribed to syphilis. It might be taken for granted that nowadays primary syphilis was never fatal, though in the past it had been so in some cases, from sloughing, sepsis, &c. Secondary syphilis was rarely fatal, though the writer had made a post-mortem examination of one such case, and it might also indirectly lead to death by suicide on account of the mental depression it sometimes caused. In the same way the mental and physical depression might indirectly predispose to infection with tubercle. Practically, deaths due directly to syphilis were always caused by its tertiary manifestations. These used to be thought to be of late occurrence, but this was now known not to be the case, and in the great majority of instances they developed within ten years of infection—in many within the first year or two. The frequency of tertiary symptoms might be taken at about 10 per cent. of all cases of syphilis, and in an average case of tertiary syphilis life was shortened by about ten years. Only a small part of the mortality of the disease, however, was due to the tertiary lesions, most was due to tabes, general paralysis, aneurysm, cirrhosis of the liver, &c. Tabes was due, in at least 75 per cent. of cases, to syphilis, and in a series of his cases in which the exact date of the infection and that of the onset of the symptoms was known, it appears that in 15 per cent. of the cases these arose within five years, in 40 per cent. within ten years, and in 67 per cent. within fifteen years after infection. In thirty-two fatal cases of tabes the average duration of life from the onset was 8·8 years, and in the seventeen of these in which the date of infection was known it was found that the expectation of life at that date exceeded the actual duration by an average of fifteen years. As regards general paralysis he had no statistics of his own to go upon, but taking the mortality in the Scottish Widows' Fund, and assuming that the infection was contracted at the same average age—twenty-seven—as in his later cases, the average diminution of life was nineteen years. Aneurysm was very often due to syphilis, and so was aortic disease; in fact, where there was no evidence of rheumatism it was almost always probably syphilitic. He thought that the combination of gout and syphilis was very unfavourable, and that it was not unlikely that if an alcoholic man was also syphilitic he was much more likely than a non-syphilitic to suffer from cirrhosis of the liver. He also laid great stress on the less-known degenerative results of syphilis. The far-reaching character of the disease must profoundly alter the tissues and render them more liable to the inroads of disease. Such was seen when prolonged worry induced the onset of general paralysis in a syphilic. Waxy disease was, as was well known, also due on many occasions to syphilis. In conclusion, he thought that syphilis undoubtedly shortened life, but how far it was now impossible to say. Since the mortality is always indirect, a statistical inquiry by assurance offices would be long and difficult, but would be possible, and he strongly urged that such should be undertaken. Among points which might be discussed, Dr. Bramwell enumerated—(1) The influence of mercurial treatment in preventing tertiary and para-syphilitic lesions. (2) Does the severity and persistence of the secondary symptoms afford a guide as to the probability of subsequent tertiary and para-syphilitic lesions? (3) When a history of syphilis is disclosed, the importance, for the purposes of assurance, of regarding:—(*a*) The physique and constitutional tendencies; (*b*) the family history; (*c*) the health of the proposer's children; (*d*) the habits; (*e*) the occupation, circumstances, and surroundings of the proposer.

[a] Abstract of a Paper read before the Edinburgh Royal Medico-Chirurgical Society, December 3rd. Report of proceedings will be found in another column.

RADICAL CURE OF HERNIA IN YOUNG CHILDREN. (*a*)

By D. KENNEDY, F.R.C.S.I., L R.C.P.I.,
Surgeon, Children's Hospital, Dublin.

Although the operation of "radical cure of hernia" seems to have been brought as nearly perfection as possible, and, although most surgeons will not treat hernia in adults nowadays otherwise than by operation, yet young children with rupture are almost invariably left for treatment to the tender mercies of the instrument maker. The principal reasons for this appear to me to be, first, a hope that the wearing of a truss will in time effect a cure; secondly, that the operation for radical cure in children is considered dangerous, and consequently should only be resorted to in very exceptional cases. Both these reasons I hold to be fallacious, and the hope of doing something to dispel that fallacy is my excuse for this communication to you to-night.

With regard to hernia in children being cured by wearing a truss, I am of opinion it is the exception, and not the rule. Although a cure does occasionally result after years, I hold the treatment by operation is far less dangerous and far more surgical than treatment by trusses; because, so long as a child has a necessity for wearing a truss, so long is he exposed to the danger of the hernia becoming strangulated. And, besides this danger of strangulation, there are many and grave objections to a child being condemned to wear a truss for an indefinite period. Principally among these objections are (1) The truss causes a great deal of irritation about the groin, ending very frequently in troublesome eczema. This irritation makes the child irritable and fretful, and consequently prevents thriving. Secondly, it is impossible to prevent the truss getting sodden with urine and fæces, and it becomes, in consequence, most objectionable and dangerous. Thirdly, the pressure of a truss, strong enough to keep up an ordinary hernia, prevents the muscles from developing in the neighbourhood of the inguinal canal, and consequently, the abdominal wall is weakened, and large ruptures are liable to occur later in life. Fourthly, the expense of getting a truss frequently, as will have to be done as the child grows, is sometimes more than poor people can bear. But, the greatest of all objections to a truss in a child is that it is rarely effectual in keeping up a hernia, and then it does more harm than good. I have met many such cases with the hernia down, and kept down so long as the truss was worn.

These difficulties in connection with a young child wearing a truss are quite apparent to anyone who does much practice with children. And in proof of this I will refer you to the article on hernia in the recent surgery by Cheyne and Burghard. The writer of that article lays down that it is rarely an infant can wear an ordinary truss; consequently, he recommends as a substitute, either a skein of worsted or a flannel bandage, to be changed, of course, as often as the child micturates. I think, gentlemen, this may be called grandmotherly surgery, and I am sure would not commend itself to me nor to the mothers of the children. The only solution is early operation, and what I mean by early, is, any time from the fourth month onward. The earlier done, the more perfect the cure, the less liability to recurrence, and the better development will there be of the abdominal muscles.

With regard to the dangers of the operation, they are to a large extent imaginary outside those which exist in the same operation with adults. I have carried out the operation on at least sixty cases under five years of age, and at least a dozen of these were under twelve months old. I never had a death, never had any sepsis, beyond rarely a stitch abscess; the patients all left hospital between the ninth and fourteenth days, and although I have made many inquiries about the children since operation I know of no case of recurrence. What I have heard invariably was, that the children were much quieter and throve much better after than previous to operation.

I will not weary you with the details of these cases, as repetition becomes monotonous, but will give you some particulars of the younger ones.

Case I.—T. K., æt. 5 months, came to me from Templemore last March. He was suffering from large double inguinal herniæ and phimosis. Both herniæ were present from birth, and the mother of the child told me a truss was quite ineffectual, though her doctor had procured her several. I admitted him to the private ward in Temple Street Hospital, and the day following operated on the right side. I found a large congenital hernia, with a very thick sac. I reduced the hernia, opened the sac, and then I found lying in the sac a very large vermiform appendix. Afraid kinking might occur if I reduced this appendix, and also afraid that it would hardly have room in the infant's abdomen, I resected it. I then, after dealing with the sac and canal, closed the wound and healing was perfect in eight days. Two days subsequently I operated on the left side, when I found an infantile hernia, the sac within sac variety, and at the same operation I performed circumcision, and ten days afterwards, that is, twenty days from his first operation, I showed the little patient here at the Academy, with his vermiform appendix in a bottle. Since that time he has never looked back.

Case II.—J. D., came to Temple Street Hospital, suffering from right inguinal hernia and phimosis. The little patient was six weeks old, was emaciated, and the mother told me very irritable. He wore a truss, which was not effectual in keeping up the hernia. The mother told me that she tried several trusses, without any better result. I circumcised the child, and gave instructions to have him back in three months' time. This was done, when I carried out a radical cure, and the child left on the ninth day, being then perfectly well, and under five months old.

The subsequent history of this child is interesting. Six months after operation I was sent for to go and see the child to his home, and was told the rupture had returned. I found a rupture, but on the other side. I again had him admitted to Temple Street Hospital, and I again carried out the radical cure with perfect success. Since that time, about eight months ago, he has had no trouble as far as I know. I was told that after birth the child had both ruptures, but that

---

(*a*) Paper read before the Surgical Section, Royal Academy of Medicine in Ireland, November 14th, 1902.

after a few weeks the left one disappeared, and only appeared again when the child began to make efforts to walk.

Case III.—Infant, æt. 6 months, sent to the Children's Hospital by Dr. Brew, of Bray. The child suffered from inguinal hernia, and a note was sent by the doctor saying that a truss was ineffectual. I carried out a radical cure, and the child left hospital on the eleventh day, his wound completely healed.

Case IV. — A girl, æt. 3, suffering from a large umbilical hernia, sent by Dr. Lyons, of Dunlavin, with a note requesting operation to be performed. I carried out the operation, resecting a large flap of skin with the hernial sac, vivified the edges of the opening in the abdominal wall, and united it by sutures of silkworm gut passed through all the layers, including the peritoneum, as after a laparotomy; the child left hospital in a fortnight perfectly well.

Case V.—A. D., æt. 16 months, came to the outpatient department of the Children's Hospital; his mother said that he was very ill. He suffered from left inguinal hernia, and was wearing a truss. On examination I found the hernia strangulated and admitted him at once to the hospital. Taxis failing to reduce the hernia, chloroform was administered, and I did herniotomy, at the same time carrying out the radical cure. The child was very ricketty and emaciated, and could not be kept quiet after the operation. In consequence hæmorrhage occurred into the scrotum, and twenty-four hours afterwards sloughing of the scrotal tissues appeared imminent. I again put him on the operation table, chloroform was again administered, and I removed the testicle, leaving the wound in the scrotum to granulate. His hernia wound healed by first intention, and he subsequently made a perfect recovery. I met two other cases of strangulated hernia, without any gangrene in the bowel being present, on both of which I operated, and both of which made an uninterrupted recovery. In these three cases of strangulated hernia, the patients wore trusses.

Case VI.—Just three weeks ago, as I was leaving Temple Street Hospital on a Thursday morning, I was asked to see a child in the waiting-room. The mother told me the child was ruptured and that he was ill all night; that he was vomiting, seemed to be in great pain, had no motion from the bowels for twelve hours in spite of a dose of castor oil, and passed no urine. On examination I found a very large scrotal hernia on the right side, completely irreducible. The infant looked very ill, and all the evidences of a strangulated hernia were present. I explained to the mother that I would have to administer an anæsthetic to the child, and that, failing a reduction of the hernia, I would operate. She left the hospital to get the consent of her husband, taking the infant with her, and did not return till the following morning. She was then agreeable to anything necessary being done with the child. When I saw him again, he looked dying. The mother told me all the symptoms had persisted during the previous day and night, and was most positive the child had passed no urine for thirty-six hours. I had him brought straight to the operating theatre and operated. I found a congenital hernia, strangulated at the neck of the sac. The bowel was discoloured but not gangrenous, and behind the bowel I found again an enormous vermiform appendix. After reducing the bowel I resected the vermiform appendix, closed the sac and the inguinal canal in the usual manner, and I am happy to tell you the child has made an excellent recovery. It is only eight months old. In this operation, as in many of the others, I was ably assisted by my friend and colleague Dr. Lewis More O'Ferral. The operation lasted about forty minutes. There was no urine in the bladder at the time of operation.

From these cases you will see that there is little to be apprehended from carrying out the "radical cure" in infants or young children. There are, however, a few points which appear to me to be essential to the success of the operation. First, no hæmorrhage should be allowed to take place; secondly, the operation should be carried out as quickly as possible, consistent with attention to details, and in a thoroughly aseptic manner; and, lastly, the anæsthetic should be properly administered. I especially insist that the child is not allowed to become half conscious at intervals during the operation, as I believe this to be productive of great shock. I have the child fully under the influence the whole time. I invariably use chloroform. Collapse after the operation has been conspicuous by its absence. Pain was not usually present to any great extent, and, if present, was easily relieved by small doses of chloral hydrate.

Contrary, I daresay, to your expectations, and, I may add, to custom, I am not going to describe or discuss any new method of dealing with either the sac or canal, which will in future be known as Kennedy's operation. I carry out as simple a procedure as possible. I never allow my skin incision to go to the scrotum; I ligature and resect the sac, and use no means to fix it in the abdominal wall; I close the canal, after McEwen's method, and I do not displace the cord. I invariably circumcise the child. In dealing, however, with congenital hernia I met with an unexpected difficulty in my earlier cases. This was due to the complete union of the elements of the cord with the posterior wall of the hernial sac, making it impossible to separate one from the other. I have found this condition present in every case of congenital hernia I have operated on, and, in consequence, I have long since given up attempting to isolate the sac from the cord in these cases. This is a condition not usually dwelt on in textbooks, or by men who have described methods of "radical cure of hernia." It seems to me impossible in these cases to carry out the twisting or invaginations of the sac, which are so elaborately described by some operators, or even to have the sac ligatured in its entirety. I would like to have the opinion of the members of this section of the Academy as to what is best to be done in these cases. I draw down the sac as well as possible after freeing it round the internal abdominal ring. I transfix it, and pass a ligature in front of the cord, as high up as I can get, I then divide the sac transversely above the scrotum, leave the lower part to form a tunica vaginalis, and dissect away all I can of the part lying in the inguinal canal below the ligature. This practically leaves the posterior wall of the sac as it was before.

With regard to the after-treatment I have little to say. I cover the dressing and bandage with protective. There is usually no need to change the dressing oftener than every second or third day. I usually fix the child in a Bryant's splint; this keeps him quiet, and materially assists the nursing. I remove the stitches on the sixth or eighth day, and, needless to tell you, I do not recommend a truss to be worn for any time whatever.

In conclusion, I may say that I did not adopt this method of operating on almost all cases of hernia in children without giving treatment by trusses a fair trial. The results were most disappointing. It was a continuous go from me to the truss maker, and from the truss maker back again to me. On the other hand, the more cases I have operated on, the more pleased I am with the results, and the more determined I am to "throw" trusses, like "physic, to the dogs."

PURULENT MEDIASTINITIS.

By PROFESSOR KOPFSTEIN,
Of the University of Vienna.

THE subject of my paper is "Mediastinitis," and more particularly the form which has run on to suppuration in the anterior space. Inflammation in the anterior mediastinum may, of course, be due to several causes, and the process involves a number of important structures, such as the remains of the thymus, the ascending aorta, the superior vena cava, the innominate veins, and the phrenic nerves. The inflammation may arise from neighbouring structures, such as the heart, or posterior mediastinum, which are also subject to acute inflammatory changes, the latter often arising from carcinomatous ulceration of the trachea and œsophagus, or the ulcer may be caused by perforation of some oreign body. There are also congestions, abscesses, and other morbid changes which often take place in the spinal vertebræ.

I am enabled to bring before you four cases which recently came under my own observation in which I operated.

The etiology of these cases may be classed under three heads, viz., injury, surroundings, and infection, or, more properly, metastases.

All these causes may give rise to purulent mediastinitis, and all of them may subside by resolution without pus formation, although Hare, who has carefully examined the whole of the literature on the subject, finds records of 115 cases of purulent inflammation in the anterior mediastinum and only sixteen non-purulent.

According to Hoffman traumatic mediastinitis becomes purulent much less than any of the other forms. Goodhart, however, records a very acute case of mediastinitis with bilateral pleuritis and pericarditis which ended in suppuration. The patient was fifty-seven years of age, and had had an accident, a piece of timber striking him on the left side of the chest. Hoffmann relates another interesting case, that of a male, æt. 27, who began to complain of pain over the region of the sternum, due to pressure from a stud in his shirt. The skin was red over the sternum, but no active lesion was found on the skin. In the course of three weeks after this occurrence high fever with swelling about the whole length of the sternum appeared with slight crepitation. An incision was made at the side of the sternum and pus was evacuated, and the whole space cleared out, but the patient succumbed from sepsis at the end of the fourth week. The post-mortem revealed purulent matter in the whole of the cavity with pericarditis, but nowhere could the origin be located.

A very common cause is to be found in the second class, where a neighbouring organ, such as the pleura or pericardium, becomes implicated, and this directly involves the mediastinum by purulent or pathogenic matter which may be conducted thither by the blood or lymphatic vessels. Phlegmon of the trachea is a not uncommon cause, as the pus can readily pass along the layers of fibrous tissue to the mediastinum. The fibrous sheaths along the large vessels, such as the common carotid, the jugular veins, &c., are also sources of danger to this prævisceral space, which may also be involved by inflammation of glands, larynx, trachea, or any inflammation of tissues about the hyoid bone. The sequelæ of other diseases, such as caries, tubercle, perforation, &c., &c., may also give rise to mediastinitis.

We now come to the third class of causes, which includes all the specific, as well as the non-specific fevers, such as rheumatism, pneumonia, &c.

The symptoms are usually associated with pain over the sternal region radiating through to the dorsal surface, and locating itself more particularly between the shoulders. This symptom must be interpreted with care, as an abscess in the posterior mediastinum will also produce pain between the shoulders which may appear to give rise to irritation of the intercostal nerves. Another symptom is intense pain experienced at every cardiac systole. In acute cases there is generally fever, rigors, and perspiration. The whole course is usually acute when there is no pus adhesion form followed by shrinking and consequent displacement of the heart. On the other hand, when pus forms, breathing is laboured and shallow, with an irregular pulse. If no issue be mechanically afforded, pus may point at the side of the sternum in one of the intercostal spaces, or the abscess may perforate the trachea, bronchi, lung, pleura, or pericardium. Very few of these cases recover. The tuberculous form is attended with the least pain.

The diagnosis is admittedly very difficult, depending largely on the previous history, but the presence of pain and fluctuation may assist. The prognosis, under any circumstances, is usually bad, as death by sepsis or perforation of an important organ determines a fatal result.

The treatment must of necessity be largely empirical until pus has formed and the diagnosis conclusively proved. The first step would be a "Priessnitz" compress over the sternum. Galenus suggested trepanning the sternum and exploring for pus. When fluctuation appears in any of the intercostal spaces it should be early opened and the abscess evacuated, enlarging the opening as far as possible. With this object Heyfelder has practised resection of the sternum in fifteen cases with the best results. Milton has sawn through the sternum in the middle and chiselled a portion out on both sides.

PURE ETHYL CHLORIDE
AS A
GENERAL ANÆSTHETIC,
WITH SPECIAL REFERENCE TO ITS USE IN MIDWIFERY.

By JAMES BURNET, M.A., M.B.EDIN.,
M.R.C.P.EDIN.
Formerly Resident Physician, Royal Infirmary, Edinburgh.

ETHYL chloride is produced by heating ethylic alcohol with H.Cl. under pressure. Its use as a local anæsthetic has been known for some time, but quite recently it has been used for purposes of general anæsthesia in its chemically pure form. Absolutely pure ethyl chloride is technically known as kélène.

Some time ago Dr. H. F. Parker published a short account (*a*) of its use as a general anæsthetic in 140 cases. In August he wrote an article (*b*) confirming his previous experience of the drug. He had seen altogether 500 operations performed where kélène was used, and in only a small percentage was it found lacking. He mentions incidentally that it should prove useful in obstetric practice. With a view to testing its suitability in midwifery I have administered it in six consecutive cases. It must be admitted this is a very small number from which to make practical deductions; still, I am anxious to give my experience that others may be induced to make trial of this new anæsthetic for themselves in their midwifery practice.

Four of the cases were multiparæ, the other two were primiparæ. In three of the cases forceps were

---

(*a*) "St. Bart.'s Hosp. Journal," Feb., 1902. (*b*) *Ib.*, Aug., 1902.

used, while in the other three the anæsthetic was administered in order to relieve the patient's sufferings. It must be understood that the cases were not selected in any way, but represented a fair average, such as any general practitioner might be called upon to attend.

The method of administering the kélène was that adopted by Malherbe, of the Hôpital Trousseau, Paris. A pocket handkerchief is folded four times in order to form a compress, which is then placed flat in the palm and 5 c.c. of the anæsthetic sprayed upon it. The palm, with the compress resting on it, is placed over the patient's nose and mouth. A mask, however, is sold for special use in administering kélène, but as I had not one in my possession I resorted to what I consider the simplest and at the same time the safest of methods.

The first case in which I used kélène was in a 3-para. On arrival at the patient's house I found the head presenting and pretty low down. As she kept calling out for chloroform I administered 5 c.c. kélène. In one minute she was sufficiently under its influence to admit of forceps being applied to the head. I had some little difficulty in applying the second blade as the patient moved about a good deal. In ten minutes the child was born. She had altogether 10 c.c. of kélène. Other two of the cases were primiparæ. In one I gave kélène in order to relieve the sufferings of the patient as the head was being born. I found 5 c.c., followed at a short interval by 3 c.c., sufficient. The patient told me afterwards that she felt no pain whatever after I administered the anæsthetic. The second primiparous case is interesting in some respects, as here kélène was used as a preliminary to a somewhat prolonged chloroform anæsthesia. The patient in this case had a narrow pelvis. She had been in labour for twenty-four hours. The cervix was with difficulty got to dilate. As the head was presenting and no progress seemed to be made, after waiting for two hours I decided to apply forceps. She was given 5 c.c. of kélène. The anæsthetic, however, did not seem to produce the same muscular relaxation obtained after chloroform. With considerable difficulty I got the lower blade in position, but by this time the patient was becoming restless. She accordingly was given another 5 c.c. This enabled me to apply the second blade. Traction was then commenced for five minutes or so; the patient seemed quite unconscious, but soon after this she began again to struggle. As the case was hardly suitable for further experimentation seeing I was working single-handed, I decided to use chloroform. The first whiff brought the patient fairly well under its influence, and though she was kept anæsthetised for nearly two hours, traction being made on the head at intervals, she made an excellent recovery. The patient certainly seemed to require less chloroform than is usual in such cases, and there was less after-sickness, in fact, in this patient's case the sickness was scarcely worth mentioning. I need hardly add that she made an excellent and rapid recovery.

The other three cases were multiparæ, in one of which forceps was used, and in the other two cases I merely gave the anæsthetic to soothe the patient and to render her pains less intense, more particularly while the head was being born. Working, as I was forced to do in all these six cases, without any assistance, save what was given by the nurse in attendance, I was unable to make use of kélène so extensively as I should have wished. More especially is this to be regretted in the case of the primipara, where I had to resort to chloroform for this very reason. Then again, it must be remembered that I had no mask. In four of my cases I was able to estimate the pulse, and in no instance did I find any marked interference with its character. Respiration likewise was unaffected. Only one of the patients showed slight signs of mental excitement, but as she was a very nervous woman I do not think the anæsthetic was altogether responsible for this manifestation.

The special point which I wish to emphasise is that I did not obtain such complete muscular relaxation with kélène as obtained by using chloroform. This was particularly noteworthy in the cases where forceps were applied. At the same time, however, I feel certain that where the patient has to be kept under the influence of an anæsthetic for any length of time it would be a distinct gain to start with kélène, and after this preliminary state to resort to chloroform. Less of the latter will then suffice, and much valuable time will be saved in the preliminary stages. The anæsthesia produced by kélène is wonderfully rapid. I should say that less than two minutes suffice to reduce the sensibility of the patient. It is very important that the patient should breathe only air charged with ethyl chloride vapour, as, if pure air is mixed with it, then the anæsthesia will take a much longer time to produce. A proper mask is therefore very useful; but for midwifery practice, in my opinion, is not altogether indispensable. The best time to begin the administration is when the patient has a "pain," as she is then inclined to cry out, and in so doing breathes deeply, and so inhales more of the vapour.

After my short experience with this comparatively new drug, I prefer chloroform for ordinary cases; but where the case is likely to prove a long one, and the patient requires an anæsthetic, I should feel justified in starting off with kélène preparatory to chloroform administration. For minor operations pure ethyl chloride is an ideal anæsthetic. Its action is rapid, and its administration safe and pleasant for the patient.

OBSTRUCTIVE DYSMENORRHŒA.

By ALEXANDER DUKE, F.R.C.P.I.

No complaint to which the human female is liable can give more pain and distress than dysmenorrhœa, the most common form being the obstructive. The best treatment and the one affording the most lasting relief, and in very many cases permanent cure, is dilatation of the entire cervical canal, and the wearing of an intra-uterine stem pessary in order to maintain that dilatation for a considerable period. I have now had a fair amount of experience in the treatment of this feminine affliction, and several years ago I designed a rapid uterine dilator, which in my own hands has given good results, combined with the use of my spiral wire uterine stem, to keep the canal patulous and retain the dilatation necessary to the cure.

This I consider the all important point. I have seen cases in which both incision and dilatation had been practised sufficiently to admit index finger into uterus, which, in a few months' time was quite as bad as ever, and pain as severe at periods as before operation.

Not long since I read a paper of Dr. Herman's on this subject, in which he states, "The local treatment of spasmodic dysmenorrhœa is to dilate the cervix, this is best done by the passage of bougies." May I ask has he tried every other plan? I regret to say I cannot agree with his statement, as I consider if the amount of dilatation necessary can be gained (as I maintain it can) by the use of an instrument, it will be a great improvement on being obliged to use several (the frequent insertion and withdrawal of such straight solid dilators into a curved and stenosed cervix, the most tolerant uterus will naturally resent).

I quite agree with the statement made by the late Lawson Tait: "It means sitting by the bedside of the patient for hours, and exercising a deal of force to the exhaustion of himself as well as the infliction of much pain on the patient."

I have always held that in order to obtain a permanent cure in these cases we must conquer for good all the uterine spasm and contraction, and I know of no better plan than rapid dilatation and the direct subsequent insertion and wearing of my "spiral wire stems" till such are no longer gripped, but will move freely up and down in cervix (the time, of course, varying in different individuals), when it can be removed. And I make bold to say that the effect of the sustained dilatation will be far more lasting, and more likely to end in permanent cure than intermittent dilatation with bougies even at a month's interval.

Another advantage I claim for stems is their action as drainage tubes, and straightness of any flexion that may co-exist; the drainage often curing the endometritis commonly observed in these cases.

As a rule, patients of mine are entirely free from pain while stem is in position and kept clean; and in two severe cases of "membranous dysmenorrhœa" no membrane whatever was observed (the next period) after introduction of stem or while worn, and one of the two (wife of a medical man) conceived and bore a son.

As I have stated elsewhere, "I have had patients wear the stems for over a year (inspected by me of course at intervals) without the smallest discomfort, and some ride the bicycle utterly unconscious of the presence of any foreign body (which, I think, could not be said of any other form of uterine stem with which I am acquainted).

A catheter tied into a male strictured urethra, for even a short time, will do more to dilate the stricture than the introduction of same at frequent intervals; and a spiral wire stem (if the proper size be chosen) will dilate, and keep dilated (at least so long as worn) a cervical canal, giving free exit to the secretions and menstrual discharge, and ensuring more lasting results in addition when removed than any other treatment for obstructive dysmenorrhœa with which I am acquainted.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.

Mr. Peter Horrocks, President, in the Chair.

Meeting held Wednesday, December 3rd, 1902.

SARCOMA OF INVERTED UTERUS.

Dr. W. C. Swayne (Bristol) showed a specimen from a nullipara, æt. 17, who was admitted to the Royal Infirmary, supposed to have been recently in labour. On examination a tumour was found projecting from the vagina, which proved to be the inverted uterus covered with a large soft growth and associated with a large vesico-vaginal fistula. The patient was extremely weak from hæmorrhage, &c. The growth proved to be a mixed-cell sarcoma. In view of the probability of there being metastatic deposits surgical intervention was not considered advisable, and she sank and died. Post mortem, no metastatic deposits were found, and there was no obvious reason why the growth should not have been removed. The uterus was completely inverted, and its body replaced by a growth. Specimen shown.

CYSTIC FIBROID OF BODY OF UTERUS.

Dr. Swayne also showed a specimen removed from a multipara, æt. 52, who came complaining of metrorrhagia with fœtid discharge. She was extremely debilitated, and there was an abdominal tumour reached to within three fingers' breadth of the umbilicus, soft and doubtfully fluctuating. He explored the uterine cavity and then curetted, but the hæmorrhage recurred within a fortnight. He then performed panhysterectomy, and while dragging the tumour through the wound a large amount of fluid escaped, and on tapping he withdrew 25 fl. ounces. The fluid came from a large cyst, and there was much myxomatous degeneration. The patient was doing well.

Dr. Griffith suggested that it would be interesting to have a complete drawing of the appearances of the inverted uterus.

Dr. Spencer asked what was supposed to be the cause of the fistula. He was disposed to question whether the growth was really a sarcoma. On examining the sections he did not feel sure that the growth was not an ordinary fibroma of the uterus, and this view was supported by the absence of metastatic deposits, which were practically always present with sarcoma.

STREPTOCOCCAL ICTERUS IN A CHILD.

Dr. Sikes showed a specimen from an infant, a few days old, under the care of Dr. Pollock. The mother was admitted to Queen Charlotte's Hospital a few days before delivery with a "bad cold," and the child displayed the same symptoms, and six or seven days after birth developed severe jaundice to which it succumbed. Post mortem, the liver and spleen were found to be very slightly enlarged, and bacteriological examination showed numerous streptococci. The sections of liver substance showed much pigment. The case was reported as one of streptococcic jaundice with great accumulation of bile in the body.

FIBROMA OF THE OVARY.

Dr. Arthur Giles showed this specimen, which was removed from a married woman, æt. 30 The patient had been married six months, and for five months had suffered from menorrhagia, pelvic pain, bladder disturbance, and obstinate constipation. On examination she was found to be suffering from multiple uterine fibromyomata, and abdominal hysterectomy was performed. The right ovary was then found to contain a solid tumour the size of an egg, and was removed with the uterus; the other ovary was left behind. The chief points of interest about the ovarian tumour were, first, its association with uterine fibroids; secondly, the well-developed capsule of ovarian tissue, which Dr. Fairbairn had shown to exist in almost all these cases; thirdly, the close association of the growth with the inner pole of the ovary and the ovarian ligament. Microscopically it presented the structure of a pure fibroma. The patient made a satisfactory recovery.

A CONTRIBUTION TO THE NATURAL HISTORY OF DYSMENORRHŒA.

Dr. G. E. Herman and **Dr. H. Russell Andrews** compared a number of cases of dysmenorrhœa cured by dilatation of the cervix with a number of others in which dilatation of the cervix produced no benefit. They find no reason to think that dysmenorrhœa curable by dilatation is frequently associated with imperfect development of the uterus. Also that dysmenorrhœa curable by dilatation begins with the establishment of menstruation in about two-thirds of the cases, and is acquired later in about one-third; that it almost always begins before the age of twenty-five, but may be acquired at any age. They find that the result of treatment is not materially affected by the length of time the dysmenorrhœa has lasted, the age of the patient when treated, or the duration of her married life. In most cases cured by dilatation the time of commencement of pain is very near the time of commencement of the flow, while in most of the cases not cured by dilatation the pain begins two days or more before the flow. In half of those cured by dilatation the pain is over in less than two days; in more than half of those not cured by dilatation the pain lasts more than four days. In four-fifths of those cured by dilatation the pain is paroxysmal; in three-fourths of those not cured by dilatation it is constant. In most of the cases cured by dilatation the pain is not relieved by lying down. The authors give details showing the severity of the pain Only a few patients were known to pass membranes, and that in only a few were there physical signs of disease. They find no evidence of such narrowing of the cervical canal as to mechanically hinder the flow of blood through it. It is possible that some degree of smallness and rigidity of the canal may hinder the physiological dilatation of the canal which should take place during menstruation, and so provoke painful contractions of the uterine body; but they are unable to adduce evidence of this. They give tables showing the known duration of cure in the cases on which the paper is based, and the number of cases in which pregnancy followed dilatation in married women who were previously sterile.

The President observed that scarcely anything in medicine or gynæcology could be reduced to a simple rule, there being so many exceptions, and the subject of dysmenorrhœa was not less difficult to classify. He thought that it was generally agreed that if the pain were intermittent dilatation would relieve, and that, he took it, implied that the dysmenorrhœa was of uterine origin. The worst forms of the disease, however, were ovarian, and then the pain was more or less constant, but, he added, there were many exceptions. He asked to what extent dilatation was carried; the condition of the uterus, and steps taken to make the dilatation permanent? In dysmenorrhœa of uterine origin he himself had dilated before an expected period up to No. 9 Hegar, and this often relieved the pain. In order to render the relief permanent he generally slit the cervix deeply down to the posterior fornix and then made a lateral incision less deeply, so as to divide the cervix into three quarters and one quarter. The great thing was to cut through the circular fibres twice. Referring to the authors' remark that the presence of membranes did not materially influence the treatment, he said that he attached great importance to membranes, and in such cases he did not think dilatation did much good. Curetting, followed by the application of carbolic acid, &c., was required. Referring to the observation that no obstruction sufficient to prevent escape of blood was ever met with in dysmenorrhœic patients, he said that short of absolute obstruction one did meet with cases in which the cervical canal was so narrow as to cause severe dysmenorrhœa. When blood clots were present in the uterus something in the nature of labour pains were required to effect their expulsion. It was not correct to say that when the body of the uterus contracted the cervix dilated, for it merely relaxed, and unless there were something to open it—fœtus, clot, &c.—it remained closed. He mentioned the case of a girl with an exceedingly rudimentary uterus—practically none at all—and no vagina, who suffered severely every month, and was cured by the removal of the ovaries. In that case, if there had been a uterus he would have ascribed to it a uterine origin. He thought dilatation and slitting the cervix should always be tried before resorting to more severe measures.

Dr. Heywood Smith believed that acute anteflexion might cause dysmenorrhœa, and insisted that the operative procedure should be to divide the internal os, because splitting the external os produced the very condition which tracheloraphy had been devised to remedy.

Dr. Boxall mentioned the case of a patient at University College Hospital, under Sir John Williams, who was kept under observation for some months for typical severe dysmenorrhœa. She had a well formed clitoris, with under-developed vagina and uterus and no ovaries at all. On opening the abdomen rudimentary testicles were found, so nothing was done and the wound was closed and the pain did not recur. He observed that with a very rudimentary uterus, if it were dilated, pregnancy might and often did occur.

Dr. Arthur Giles said that the paper served a useful and practical purpose in defining the cases of dysmenorrhœa in which dilatation was likely to prove useful. Its non-suitability in cases in which the pain chiefly preceded the flow was readily explained, because such pain was congestive in origin: and congestion was not likely to be cured by dilatation. The cause of painful contractions was obscure, and to understand them it would be necessary to know why uterine contractions during labour were painful. He was interested in Dr. Boxall's cases, but was inclined to think his experience was unusual. From a careful investigation of a number of these cases his experience was that the striking features of menstruation with under-developed uterus were late onset, scanty flow, and freedom from pain, and the patients were nearly always sterile.

Dr. Galabin pointed out a number of fallacies to which the classic symptoms might give rise, and observed that the so-called spasms of pain were often of comparatively long duration, very unlike the uterine contractions with which they were familiar.

Dr. Lewers pointed out that the absolute measure of dilatation, according to the number of Hegar, did not take them very far, because in some instances it was possible to introduce them with comparative ease up to a high number, while in others resistance was soon experienced. The dilatation proper did not begin until resistance was overcome.

Dr. Griffith said they were discussing a subject which had no definite limits. They were supposed to be discussing dysmenorrhœa, but on listening to the paper it became apparent that the authors in reality only dealt with the treatment of certain cases of spasmodic dysmenorrhœa. There was probably no subject of which the average man was so ignorant as that of dysmenorrhœa. The views held were sometimes imaginary, sometimes antique, and they were copied from one book into another without any attempt to control their accuracy. He recalled the fact that on one occasion when he showed a specimen consisting of a dilated uterus the late Dr. Graily Hewitt had expressed great interest therein, because it was, he said, the first dilated uterus he had ever seen, his own drawings having been made from clinical observation. He discussed the extreme variability of the symptoms, and urged that they were not entitled to talk of membranes or clots unless they had been examined microscopically, for patients' utterances in reference thereto were utterly untrustworthy. He had frequently demonstrated that behind the so-called "pin-hole" os there might be a normal canal. The cases of pure dysmenorrhœa without menstruation, if only they were more frequently met with, might perhaps give them a clue to the real nature of this obscure affection. He did not agree that the cases could be divided into those with backache and those with spasms nor that the backache cases were most likely to be relieved by dilatation. The difference in the intensity of the pain was probably more a matter of individual idiosyncrasy than of actual intensity, just as some women complained bitterly of after-pains, while others thought nothing of them.

Dr. Briggs (Liverpool) confirmed the value of the incision treatment, although their experience in Liverpool had not been as successful as that achieved by the authors.

Dr. Herman agreed that the intensity of the pain was largely an individual matter. He had practised dilatation of the internal and external ores with good results. He had first used dilatation in cases in which incision had failed to relieve, and even in membranous dysmenorrhœa dilatation was still the most effectual treatment, though the cure was not always permanent. Even when a clot was present they could not know for certain that it was formed inside the uterus. He did not deny that anteflexion was often present in dysmenorrhœic patients, but it was quite as common in those who did not suffer therefrom.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held December 3rd.

Sir Thomas Fraser, President, in the Chair.

Dr Edwin Bramwell showed a man who had complained of weakness in the right arm for four or five months. There was weakness and wasting of the small muscles of the hand and of the long flexors, and also a patch of anæsthesia extending along the inner aspect of the right forearm, not, however, reaching the hand. The sympathetic was unaffected, such a combination of symptoms could not be due to a lesion of the peripheral nerves, and there were no symptoms of cord affection.

On the other hand, it was quite characteristic of a lesion of the first dorsal nerve root. There was no history of trauma. The prognosis in such cases was bad.

Dr. Melville Dunlop showed a case of unusually high temperature in an infant, due to intestinal decomposition. The child was admitted to hospital with diarrhœa, the stools being very offensive. Shortly after admission a convulsion occurred, and the temperature rose rapidly to 107·2°, falling again quickly. Head retraction became pretty well marked, and in a day or two a second convulsion took place, the temperature on this occasion reaching 108.6°. The treatment adopted consisted in irrigating the bowel and giving small doses of calomel, and as soon as the state of the motions became more satisfactory the nervous symptoms ceased.

Mr. George Chiene showed an infant, æt. 8¼ months, operated on four months previously for acute intussusception. The child was taken ill suddenly one morning at 9 a.m., and was admitted to hospital a few hours later. A sausage-shaped mass, about eight inches long, could be felt in the abdomen, but the rectal examination was negative, except that some blood-stained mucus was withdrawn on the finger. Abdominal section was at once performed, and the intussusception, which proved to be of the ileo-cæcal variety, was easily reduced. The operation was completed within four and a-half hours from the onset of the symptoms.

Mr. F. M. Caird showed (1) A man whose olecranon had been wired five and a-half months after the receipt of injury, because the union was fibrous and inefficient. Some little difficulty was found in overcoming the separation of the fragments caused by the contraction of the triceps, but the result was satisfactory, and the patient could now work, which formerly he had been unable to do. (2) A female, æt. 23 years, after excision of half the tongue and the glands of the side of the neck for epithelioma of seven weeks' duration.

Mr. David Wallace showed a patient who for many years had suffered from obscure abdominal symptoms. Pain latterly most severe in the right iliac fossa, and vomiting had led to the suspicion of appendicitis, but had subsided under rest in bed. He was again admitted to hospital, however, on account of an acute attack with pain, abdominal distension, and vomiting. On opening the abdomen two feet of the ileum were found intussuscepted into the colon, and at the apex of the intussusception there was a papilloma, about the size of a pigeon's egg. Knowing that these papillomata were seldom single, the neighbouring bowel was examined, and as it contained numerous similar tumours two feet of it were resected. The patient made a good recovery.

Dr. Chalmers Watson showed the case of lupus vulgaris previously brought forward to illustrate the efficacy of the myelocene treatment. Very marked improvement has taken place, chiefly, he thought, as the result of the action of myelocene on the pyogenic organisms to which the ulceration was due.

Dr. Atchison Robertson demonstrated a stethoscope adapted for the clinical instruction of from five to ten students simultaneously. It consisted of a chest-piece to which a phonendoscope and resonating chamber were attached, and which communicated with five or ten binaural stethoscopes.

Dr. Dawson Turner showed an apparatus for the production of high-frequency currents for the treatment of malignant and other diseases. The apparatus consisted of two induction coils, the one discharging into the other, a Leyden jar intervening as a condenser. A current alternating with enormous frequency—a million or more times per second—and of thousands of volts was thus obtained. Notwithstanding its high voltage it did not produce the ordinary sensory or stimulant effects on nerve and muscle. These currents were employed in three ways: (1) As a direct local application by means of electrodes of various patterns (demonstrated). (2) By auto-conduction, in which the patient lay in a metallic cage, round which the currents circulated, not coming in contact with the patient, but setting up induced currents in his body. (3) By auto-condensation, in which the patient was substituted for the condenser, lying between, but not in contact with, two metallic plates.

The following specimens were shown:—

Mr. David Walterston: Specimens illustrating the development of the brain.

Mr. George Chiene: (1) Splinter of wood found in the stool of an infant three days after operation for intussusception. (2) Photograph of case of intussusception. (3) Portion of gut resected from a child, æt. 1¾ years, for acute intussusception. (4) Intestine of child, æt. 9 months, operated on for acute intussusception, showing commencing gangrene.

Mr. Alexis Thompson: Melanotic cancer of parotid and cervical glands.

Mr. Caird: (1) Preparations from case exhibited, showing microscopic appearances of carcinoma of tongue and glands. (2) Cæcum, ilieo-cæcal valve, appendix, and portion of ileum removed from case of tuberculous appendicitis.

Dr. Chalmers Watson, photographs illustrating the treatment of lupus vulgaris.

Professor Annandale read a paper on "Some Practical Suggestions in Operative Surgery." The following were some points of practical importance designed to overcome certain of the difficulties met with in various operations. All of them had stood the test of many years' experience. (1) In connection with certain operations upon the nose, palate, and upper lip: In cases where it was desired to improve a deformity of the nose, and where there was considerable loss of tissue, the material might be got from one of the fingers by dissecting up a flap of skin and fixing it in position. In such cases the difficulty was to fix the hand so firmly that union should not be disturbed. The best way to do this was to control the movements of the wrist by a long posterior splint which extended beyond the finger tips and was secured to the forehead by a bandage passing round the head. The arm was at the same time bandaged to the side of the body, but this latter alone would not be found enough to hold the hand steadily in position. In making a new bridge to a nose there was often difficulty in preventing the tissues from falling in after they were sutured in position. To remedy this tendency he used a saddle-shaped piece of sheet lead, moulded so as to fit the nose, which through this and the enclosed tissues of the nose a needle was thrust transversely. By having the ends of the transfixing pin or screw threaded so that small nuts could be applied, lateral pressure could also be exerted and the nose moulded at will. After many plastic operations on the nose it was found that the upper lip tended to be drawn up so as to expose the teeth. The best way to prevent this was to fix it in position by nailing it to the alveolus of the superior maxilla during the healing of the parts. In uniting a cleft palate the greatest difficulty was usually found near the anterior part of the cleft, owing to the difficulty of getting a fixed point to which to attach the flaps. It would be found a help to fix one of the flaps to the raw palate by a nail before suturing so as to fix it. (2) In connection with some operations on the air passages: In extensive operations in the mouth, &c., it was often desirable to perform a preliminary tracheotomy, and various means were employed to prevent blood trickling down into the lungs. Some surgeons packed the whole wound, and others employed a special tracheotomy tube with an elastic balloon as obturator which could be inflated so as to block the trachea. This was apt to be punctured during the operation, and to collapse. He employed solid india-rubber balls of various sizes, one of which was put through the tracheotomy wound into the lumen of the trachea above, and served effectual to block it. The tracheotomy tube was adopted to allow of a foot or two of rubber tube being attached to it, and the anæsthetic was given through this, the anæsthetist being well out of the operator's way. (3) In amputation of the penis: The best way to prevent hæmorrhage was to twist an elastic band round the root of the organ and to transfix in front of this with an ordinary bonnet pin. If the organ was not transfixed or if the skin alone was transfixed, the *corpora cavernosa* and *spongeosa* retracted at once and great hæmorrhage occurred. (4) In connection with perineal drainage of the bladder: He was accustomed to allow the end of the perineal drain to rest inside the end of a piece of lead pipe which was long enough to extend from the perineum down over the foot of the bed and ended in a vessel which collected the urine. (5) In colotomy for incurable disease of the rectum, he thought that it was advisable to divide the colon completely and stitch up the lower end. Unless this was done, however large the spur which formed a certain amount of fæcal matter was sure to escape into the rectum and give rise to discomfort. (6) In those cases of undescended testicle in which it was thought desirable to replace the organ to the scrotum, the difficulty was to keep it there after the operation. He overcame the tendency to retraction by mooring it to the skin of the thigh with a stitch which kept up the requisite tension while the wound was healing. (7) In those cases of spina bifida in which the tumour was small and pedunculated, he advised the injection of Morton's fluid along with the constriction of the neck of the sac by an elastic ligature.

On the motion of the **President**, Professor Annandale was cordially thanked for his paper.

Dr. **Byrom Bramwell** read a paper on

SYPHILIS AND LIFE INSURANCE,

an abstract of which will be found under the heading of "Original Communications," page 621.

Dr. Bramwell's paper was discussed by Dr. Ritchie, Dr. Clouston, Dr. Affleck, Mr. Low, actuary, Mr. Hodsdon, and others. The practical difficulty that a history of syphilis is almost never obtained, even in reply to specific questions on forms, was mentioned, and all the speakers agreed with Dr. Bramwell in regarding syphilis as a disease which shortened life, and that those in whom it was discovered should not be accepted at ordinary rates, and also agreed as to the importance of a statistical inquiry such as he proposed.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

Meeting held Friday, November 28th, 1902.

Dr. **Hastings Tweedy** showed the following specimens:—(*a*) Tubal Pregnancy; (*b*) Ovarian Cyst and Pyosalpinx; (*c*) Salpingitis (two cases).

Dr. **John Knott** read "Notes on a Case of Amenorrhœa."

Dr. **Elizabeth Beatty** described two cases of amenorrhœa which she had attended. One case was a very obstinate one, and had persisted for five years. Various remedies were tried, and finally treatment by electricity proved successful.

Drs. **Neill** and **McWeeney** on a case of

PUERPERAL ECLAMPSIA.

Catherine R., æt. 28, admitted on April 29th, 1902. Second pregnancy—first was natural, fifteen months ago. Patient was attended in the external department of the Coombe Hospital on April 20th by the Clinical Clerk about 10 p.m., who found her in a comatose condition, having had a severe fit. He administered ½ gr. morphia hypodermically, and had her removed to hospital without delay. On admission she was in a condition of deep coma, the contraction of the pupils however, not being very pronounced; the skin was dry, and the temperature subnormal—in the axilla the pulse being 63; she was not in labour. She was at once put into a wet pack and given croton oil ♏ j The catheter was passed, and about 7 ozs. of bloody urine drawn off. An enema of soap and water was given, which was retained. She was kept constantly on her side, and after two hours was taken out of the pack. She remained quiet until 3 a.m. of the following morning, when she had a severe fit, which lasted about 15 minutes. She was again put into the pack, and given ¼ gr. of morphia hypodermically. At 3.50 a.m. she had another fit, which did not last so long. She was then taken out of the pack, and at 4.15 had another fit; at 5.45 she was given a glycerine enema, which was also retained. At 6.30 she was again put into the pack and given ♏ j of croton oil. She remained perfectly quiet until 8.30, when the respirations were observed to be rather slow, the pupils also being dilated, the pulse remaining fairly good. She died rather suddenly and undelivered about 8.40 a.m., having remained unconscious from the time of her admission. The fœtal heart could not be heard. Percentage of urea in the urine was 0·8 per cent.

Dr. **Alfred Smith** said, in regard to its etiology, that the kidney was most frequently blamed for this disease, but he was very doubtful if this was always correct. The kidney in Dr. Neill's case was apparently normal, except for the congestion, which is frequent in cases of toxæmia, and that incompetence of the liver was probably to blame.

Dr. **Kidd** thought that a good deal might be said as to the liver being the cause, but we would wait a long time if we referred all cases of eclampsia to any one organ. He said that there must have been tremendous pressure on the ureters, but did not know if that had any bearing on it.

Dr. **Neville** said that the treatment seemed to him to be the point of interest. The strain on the right side of the heart must have been very great, and having seen a case of status epilepticus treated by bleeding from the forearm, which immediately gave very remarkable relief, he thought if it had been adopted in this case the patient might have survived the attack.

Dr. **Hastings Tweedy**, speaking of the toxæmic theory, said that Bouchard was the originator of it, and had entirely proved his case from his own point of view, but Bouchard's theory had been refuted, and now we were much less certain of the toxæmic theory. The great mistake Bouchard made was that he drew off the urine without any aseptic precautions; it is now found that every urine is toxæmic if left for any length of time exposed to the air. When drawn off with proper aseptic precautions eclamptic urine shows no toxin, and has no worse effect on rabbits, &c., than urine in normal health. The body naturally secreted poisons which had to be eliminated through the kidneys, but sometimes these organs appeared to be sluggish, and did not secrete as much as they should, and the result was seen in headaches, dyspepsia, &c., especially in women. These symptoms were cured by drinking warm water, and he thought that women should drink more fluid; the want of it was shown by headaches, then twitching, and finally eclampsia. In pregnancy not only had a woman to eliminate her own poisons, but also those of the fœtus, and this double dose, combined with the fact that her nervous system was then more excitable, made her a good subject for eclampsia. He referred to the difficulty which Dr. Neill had in getting the bowels of his patient to move with croton oil, and said that one drop was nothing; up to six or seven could be given. He thought that in some cases the poison was not in the blood, but deposited in the solid tissues, and therefore bleeding was of use, because it drew it into the blood stream. He doubted if pressure on the ureters could be the cause of eclampsia.

Dr. **Neill**, in replying, said that in these cases the kidneys were not always diseased, but that often they were. He then referred to a patient who was admitted to hospital suffering from albuminuric retinitis. She got well. She was two months pregnant, and developed eclampsia. Though she recovered from this, she became totally blind. She had five bad fits, then they ceased, and three weeks afterwards a macerated fœtus was expelled. There was a large quantity of albumin in the urine. In that case undoubtedly the kidneys were diseased. Other cases, he said, had shown large quantities of albumin, but it quickly disappeared. He never performed venesection; the patients were simply kept as quiet as possible. In nearly all the cases of eclampsia he had seen there had been very little post-partum hæmorrhage. He had seen a peculiar case in which death resulted apparently from eclampsia; the convulsions came on after the child was born. In this case there was very advanced tuberculous disease of the lungs. He said that 2 minims of croton oil were given, and at the post-mortem nothing was found in the bowels. The stomach was greatly distended with gas; the small intestine was empty. There was nothing abnormal in the abdominal cavity except the ureter, which was quite unrecognisable from its enormous distension.

CORK MEDICAL AND SURGICAL SOCIETY.

Meeting held Wednesday, November 26th, 1902.

Dr. P. T. O'Sullivan, President, in the Chair.

The **President** showed a case of ataxic paraplegia in a man, æt. 30. He said that about six months ago the patient began to complain of weakness in the lower limbs, and his gait became irregular. At present his gait was distinctly ataxic, the knee-jerk was increased and ankle-clonus could be obtained. The pupils were normal, and there was no history of alcohol or syphilis.

Dr. J. M. **Browne** showed a case of double congenital coloboma of the iris of a boy, æt. 10. In the right eye the iris alone was involved, but in the left deficiency extended back to the retina. The patient's grandfather and one of his brothers were similarly affected.

Dr. H. R. **Townsend** showed a dermoid cyst which he had removed two months previously from a child, two and a-half years old. The weight of the cyst and its contents amounted to 13 lbs., the weight of the child before the operation being 35 lbs., and immediately afterwards 22 lbs. Between six and seven pints of fluid were contained in the cyst. Immediately on removal of the tumour the patient collapsed badly, but owing to the vigorous application of restoratives by several assistants, and the rapid completion of the operation, she survived the shock and made a good recovery, and was shown at the meeting.

Several members commented on the large size of the tumour in so young a child.

Dr. J. **Cotter** showed a sarcoma of the kidney, which he had removed from a man, æt. 52. The tumour weighed 5 lbs., and had undergone cystic degeneration in parts. It was removed through a lumbar incision prolonged towards the front. A microscopic examination showed it to consist of large and small round cells, with some adenoid tissue.

GENERAL MEDICAL COUNCIL.

SEVENTY-FIFTH SESSION, NOVEMBER, 1902.

Sir W. Turner, President, in the Chair.

SIXTH DAY.—Monday, December 1st.

Report of Public Health Committee.

Dr. **Bruce**, Chairman of the Committee, brought up a report on various communications referred to them by the President, including one from the Advisory Board for the Army Medical Service, stating that the Board contemplated large and important changes in connection with sanitary administration in the Army. The Board proposed to establish a higher grade of Army medical officers, whose duty it would be to supervise the sanitary work of the ordinary Army medical staff; and it was desired that the Medical Council should sanction such additions to the present rules and regulations as would enable officers of the Army Medical Service to obtain a diploma in Public Health from any of the licensing bodies. In regard to the question of how far the scheme of education and training proposed by the Advisory Board corresponded to the regulations of the Council for candidates for the diploma of Public Health, it was stated that in the scheme the regulation as to the interval which must elapse before proceeding to the diploma in Public Health was more than safeguarded, and that, with six months' laboratory work, the scheme of the Advisory Board, as it stood, made provision for a period (in two portions) of altogether four months. Dr. Bruce stated that the Committee could not recommend any abridgment of this portion of special study as drafted in the regulations of the Council. The utmost they could agree to was that the first two months might be taken into account, but the balance of the time—that was four months—should stand. The Committee were informed that the Advisory Board should leave it optional to the candidates for these diplomas to prosecute their laboratory work at any University or medical school which possessed adequate means for prosecuting the study of the subjects required for this diploma. The Committee considered that it would be well that distinctions as between medical men acting in their capacities civil and military should, as far as possible, be removed, and suggested an addition to one of the rules with that object. They were satisfied that every medical officer in the Army had from the commencement of his service ample opportunities of acquiring a knowledge of methods of hospital administration in relation to infectious diseases They accordingly proposed that the following note be appended to Rule 4:—"In the case of a medical officer of the Royal Army Medical Corps, a certificate from a principal medical officer under whom he has served, stating that he possesses a practical knowledge of hospital administration in relation to infectious diseases, may be accepted as evidence under Rule 4."

In moving that the Committee's report be approved, Dr. Bruce pointed out that the proposed scheme was nearly parallel to the present organisation for Public Health in civil life, and it also implied a distinctly higher or honours grade of medical officers of health, which the Council had all along demanded, while not interfering with the present course followed by many Army doctors who, when on sick leave or otherwise, managed to work for and obtain a diploma in Public Health. It proposed to arrange that a limited number of military medical officers should be specially trained for such work, and it asked the Council to put the stamp of Public Health diploma upon those men who, after being examined by one of the qualifying bodies, had proved themselves fit and competent for such diploma. In recommending the acceptance of the scheme so far the only real difficulties that had troubled the Committee were (1) the limitation of the field of experience during the pupilage of the military candidates, and (2) as regarded the knowledge of sanitary law which did not come within the purview of the military authorities. But the Committee believed that an honest examination for a diploma in Public Health, properly conducted, would be a sufficient test of the candidate's fitness to hold such a diploma.

Lieut.-Colonel **Davies**, of the Advisory Board of the Army Medical Department, and Major McCulloch, the officer in the Army Medical Department who has specially to deal with sanitary returns, attended in order to give any further information that might be desired.

Mr. **Ball**, who seconded the motion, said the present Secretary of State for War had taken very great interest in the affairs of the Army Medical Department, and at Mr. Brodrick's instigation a Reorganisation Committee was formed, which Committee made very important suggestions for the improvement of their service. These suggestions were now being carried out, and they could hardly fail to attract to the service many of the better class of young practitioners. Of the reforms of a purely professional character which had, in consequence of the report, been established, he alluded first to the fact that on the site of the old Milbank Prison a staff college was being built, and also a hospital of considerable size. Laboratory instruction of the best kind would be provided at the college, which was intended not only for young officers on probation, but for officers at a later period of their service, so that officers on returning from foreign service should have an opportunity of revisiting the staff college for a further period of education. The next important point in the reorganisation scheme had been the appointment of specialists. The medical officer who showed that he was capable of really good work in any one of the many specialities that were named was encouraged to devote himself more particularly thereto by the fact that he received an increased fee if he qualified as a specialist, and that he could obtain an acceleration of his promotion on purely professional merits. Of the many special subjects the Advisory Board considered that sanitary science was extremely important. A new class of officers had been created called sanitary staff officers. For the present provision was being made for nineteen of these officers. They had no duties to perform in sanitary matters, and they would be assigned to large Army Corps districts at home and commands abroad solely to look after the welfare of the district in which the troops were stationed. In all this work the Advisory Board claimed that they could give at least as good an education as could be got in any of the civilian schools for medical officers of health. They courted the very fullest inquiry from the licensing bodies respecting their teaching, and if any suggestions could be made for improvement they would be thankfully received and acted upon. The whole desire of the Advisory Board was to make the training in sanitary science of the Army Medical Department as good and as efficient as it could possibly be.

Dr. MacAlister moved to amend the proposed addition to Rule 4 as follows: -In the case of a medical officer of the Royal Army Medical Corps, a certificate from the principal medical officer under whom he had served, stating that he has been engaged for a period of at least three months in acquiring a practical knowledge of hospital administration in relation to infectious diseases, may be accepted as evidence under Rule 4."

Dr. Bruce accepted the amendment, which was then agreed to.

Sir John Tuke, M.P., in supporting the recommendations of the Committee, said that circumstances had arisen which he thought would fully justify the alteration of their regulations. No one was more jealous than he of the regulations which had been formulated by the Council, but, in his opinion, the passing of this scheme would be a great boon to the Army. He had very good reason to believe that on certain occasions the absence of an intimate knowledge of the laws of Public Health had been productive of evil in South Africa.

The recommendations were then agreed to *seriatim*, the revised report containing them to come up for approval subsequently.

Attendance at Fever Hospitals.

A communication from the Metropolitan Asylums Board is enclosed in the report suggesting that the Council should reconsider the rule which they had recently made with reference to the attendance of candidates for the diploma in Public Health at the fever hospitals, on the ground of the difficulty which the Committee felt existed at the hospitals of that Board in giving such instruction. The Committee advised that the Board should be informed that the Council adhered to the regulations referred to, and this was agreed to.

It was resolved to send a similar reply to a communication on the same subject received from the Royal Institute of Public Health.

Two applications made by intending candidates, asking for relaxation in their case of the rules and regulations for the diploma of Public Health, were refused.

Preliminary Education.

The report of the Education Committee on the result of the steps taken to raise the standard of certain preliminary examinations was received and adopted. This report bears on the examinations of the College of Preceptors, the Educational Institute of Scotland, and the Royal Colleges of Physicians and Surgeons in Ireland. The Committee are of opinion that the standard of the College of Preceptors has reached that recommended by the Council in 1900 to come into force in January, 1902, but they are unable to give this assurance with regard to the others.

A grant of £25 was made to the Education Committee to assist them in carrying on the work.

Reports from the Examination Committee.

Apothecaries Hall, Ireland, Dublin—The Visitor and Inspector point out that at seven final examinations held under the existing regulations, thirty-two candidates presented themselves and eleven received their diplomas. On the present occasion two candidates entered and both failed. They criticise certain details, but express themselves well satisfied with the arrangements for the examination, which they describe as "sufficient." The Committee nevertheless see nothing in the report to modify the conclusion come to in December last—viz., that the candidates for this examination are men of an inferior class who seem to be incapable of passing a good examination in any important group of subjects, and can only obtain their license of practice by what the Council condemns—viz., the piecemeal method of passing examinations, long spun out. They add that the introduction of such men into the profession is not, from their point of view, to the advantage of the public.

Mr. Tichborne protested against the concluding paragraph in the report, and moved that it be deleted.

Mr. Jackson and Dr. Atthill called attention to the numerous errors of spelling which disfigured the papers, and Mr. G. Brown seconded Mr. Tichborne's amendment on the ground that the blame was hardly fair.

Sir William Thomson suggested that only the concluding part of the paragraph should be omitted, and, no objection being raised, this was agreed to and the modified report was adopted.

The Conjoint Board in Ireland.—The Visitor and Inspector make sundry criticisms and suggestions which, in the opinion of the Committee, "demand serious consideration by the bodies inspected," but the reporters state that on the whole they are of opinion that it is a fair and carefully conducted examination fulfilling the requirements of the Council.

The report was adopted and the Council adjourned.

SEVENTH DAY.—Tuesday, December 2nd.

Sir William Turner, President, in the Chair.

University of Birmingham.

The Committee "were satisfied that the examination was not only sufficient but of a high order," and they even went so far as to congratulate the newly-formed University on the result of its first medical inspection. The report was, of course, agreed to *nem. con.*

Medical Amendment Bill.

The Council then went into committee to further discuss the draft Bill. The next step was to enter upon the minutes the draft Bill as modified by previous discussion and subsequently amended by Mr. Muir Mackenzie, and this was agreed to.

This draft Bill has for object, (1) to reorganise the relation of the Central Council to the Branch Councils, (2) to abolish branch funds in favour of one central fund, (3) to revise the fees payable on registration, (4) to provide for the compulsory registration of medical students, and to levy a fee for so doing, and (5) to place the finances of the Council on a better, or at any rate on another basis.

On the motion to adopt the report, Dr. Finlay moved that the report of the Financial Relations Committee be referred back for further consideration, especially in respect of "economies in expenditure," no suggestion bearing thereon having been made by the Committee.

Dr. Norman Moore seconded, adding that it remained with the Committee to convince the Council that no economies, however slight, could be made. He thought the amendment might assist in placing the finances of the Council on a sound basis.

Sir John Tuke urged that the proper course was for the Council to lay a statement of its financial position before the Privy Council, and from this point of view the introduction of a Bill was premature and even irregular. It was the business of the Council to show that no reduction of expenditure was possible, but he urged there were many ways in which this could be effected; for instance, they had not considered the question of abolishing fees and lengthening the hours of sitting.

Sir Victor Horsley pointed out that this had been considered and it was stated in the report that it was not an economy which could be expected to meet a deficit of £1 500 a year.

Sir John Tuke argued that the Committee ought to have given their reasons. He suggested that they might shorten the procedure in penal cases and they might apply to the Consolidation Fund in the same way as the Incorporated Law Society, &c. He entirely dissented from the Bill, which he believed would be opposed by the public and also by the profession.

Sir Victor Horsley pointed out that the first thing suggested in the report was a memorial to the Privy Council. Economies were considered, but not reported upon because they were considered inadequate. He would gladly support a proposal to apply to the Consolidated Fund, and as to reduction of fees he suggested that members should have the courage of their opinions and vote for it. (Sir John Tuke: I did vote for it.)

The amendment was then put and carried. Dr. Atthill asked that Dr. Finlay's name might be substituted for his on the Committee.

An attempt by Sir William Thomson to instruct the Committee to consider the advisability of limiting the Bill to a single clause (alteration of fees) was disposed of by "the previous question."

Public Health Examination Rules.

The rules for the diploma in public health, as amended on Monday, with reference to Army medical officers, were adopted by the Council.

Report of Pharmacopœia Committee.

Dr. MacAlister, in moving the adoption of the report, referred to the International Conference for the Unification of the Pharmacopœial Formulæ of Potent Drugs and Preparations held at Brussels from September 15th to 20th last, when a number of resolutions were discussed, in which a good deal of give and take was required, but ultimately the decision of the Conference was unanimous. In order to continue and complete the work it was proposed that an international bureau should be established in Brussels for the purpose of affording to the various pharmacopœial authorities opportunities of intercommunication. The Committee believed that such an office would be capable of rendering important international services, and thought it desirable that the Council should in a formal manner support the proposal of the Conference for its establishment. The recommendation that he moved was that "The Committee therefore recommended that the President be requested to inform the Belgian Government, through the proper channels, that the General Medical Council approves the proposal to establish in Brussels an International Bureau of Information on matters relating to pharmacopœial unification, and that it is willing, when desired, to nominate a correspondent representative of the 'British Pharmacopœia.'"

Mr. Tichborne seconded.

Dr. Payne expressed cordial approval of the object of the Conference, and moved a vote of thanks to Dr. MacAlister for the services he had rendered at Brussels. This was agreed to.

The report of the Students' Registration Committee and of the Dental Education and Examination Committee were received and adopted.

Mr. G. Brown then moved a resolution which stood in his name for the appointment of a committee to consider the question of "pupilage," but he admitted that it was so drafted that it could not profitably be discussed, and asked leave to withdraw it, which was promptly accorded.

The English Conjoint Board.

Sir Victor Horsley asked the Council to express the opinion that the Royal Colleges had had time to communicate their observations upon the report of the Visitor and Inspector upon the first examination of the Conjoint Board, and ought to have furnished the Council with their observations thereon. After some discussion this was shelved by "the previous question."

The President was requested to appoint two persons to visit and report upon the examination in chemistry, physics, and biology of the Conjoint Boards in Scotland and Ireland and the Apothecaries Society in London.

Circulation of Council Documents.

Sir Victor Horsley moved that a confidential copy of the reports of the visitors and inspectors should be supplied when ready to members of Council, together with a copy of the remarks thereon by the body visited. This was negatived by a majority of one.

Proposal *in re* Legislation.

Mr. Tomes moved that an endeavour be made to secure the interest of the Government in Bills promoted by the Council, and this was agreed to.

Various items of business were transacted, and after the usual votes of thanks the session came to an en

Special Articles.

OPENING OF THE NEW MEDICAL INSTITUTE IN BELFAST. (a)

On Wednesday, the 26th ult., the new home of the Ulster Medical Society, described in these columns a few weeks ago, was handed over to the Society by Sir William Whitla, by whom it has been built, furnished, and equipped. The day's proceedings consisted of three functions—the opening of the Institute by the Lord-Lieutenant in the morning; the unveiling of the Smyth memorial window in the afternoon; and the annual dinner of the Society—the first under its own roof—in the evening.

At the morning ceremony the spacious lecture-hall was filled with a representative gathering of medical men from all parts of Ulster. On the arrival of their Excellencies, President Hamilton, of Queen's College, was moved to the chair, and explained briefly the position of the Ulster Medical Society and the Belfast Medical School, and pointed out the great advantages that would accrue to both from Sir William Whitla's gift.

Sir William Whitla, who was very warmly received, handed the title deeds of the Institute to Dr. John Campbell, who succeeds him as President of the Ulster Medical Society. In doing so, he said that he made no conditions or restrictions whatsoever, save that the building be used as an institute or place of meeting for the Society, in which medical men of the city of Belfast and the province of Ulster might from time to time assemble and discuss the many problems which relate to the healing and prevention of diseases, and all matters which pertain to the health of the community in which we lived. "It is," he added, "my sincere hope that under the guidance of Him who went about healing all manner of diseases, and to whose service I humbly in my heart dedicate this building, that the increased facilities which it affords will stimulate original research, and to some extent assist the general advance of our sacred mission for the alleviation of human suffering. I am also hopeful that it will consolidate and strengthen the feeling of brotherhood which has always been a characteristic of our profession in this northern province." The following Fellows of the Ulster Medical Society were named as trustees of his gift by the donor:—Dr. John Campbell, Dr. Nelson, Dr. Dempsey, Professor Lindsay, Dr. McCaw, Dr. Mitchell, and Dr. Cecil Shaw.

Sir William Whitla then handed a massive silver-gilt and enamel key to his Excellency, who, amidst much enthusiasm, declared the Institute open. After expressing his pleasure at being present, the Lord Lieutenant referred to the graceful way in which the gift of the Institute was made, saying that the spirit in which it was given at any rate equalled the generosity of the gift. He concluded by expressing the hope that for many years to come the Institute might be a source of benefit to the medical profession, and that lecture-room might be the scene of great developments in medical science and medical discovery.

A vote of thanks to their Excellencies was moved by Professor Redfern, seconded by Sir Jas. Musgrave, and passed by acclamation.

Dr. John Campbell moved, on behalf of the Ulster Medical Society, that their best thanks be given to Sir William Whitla for his generous gift.

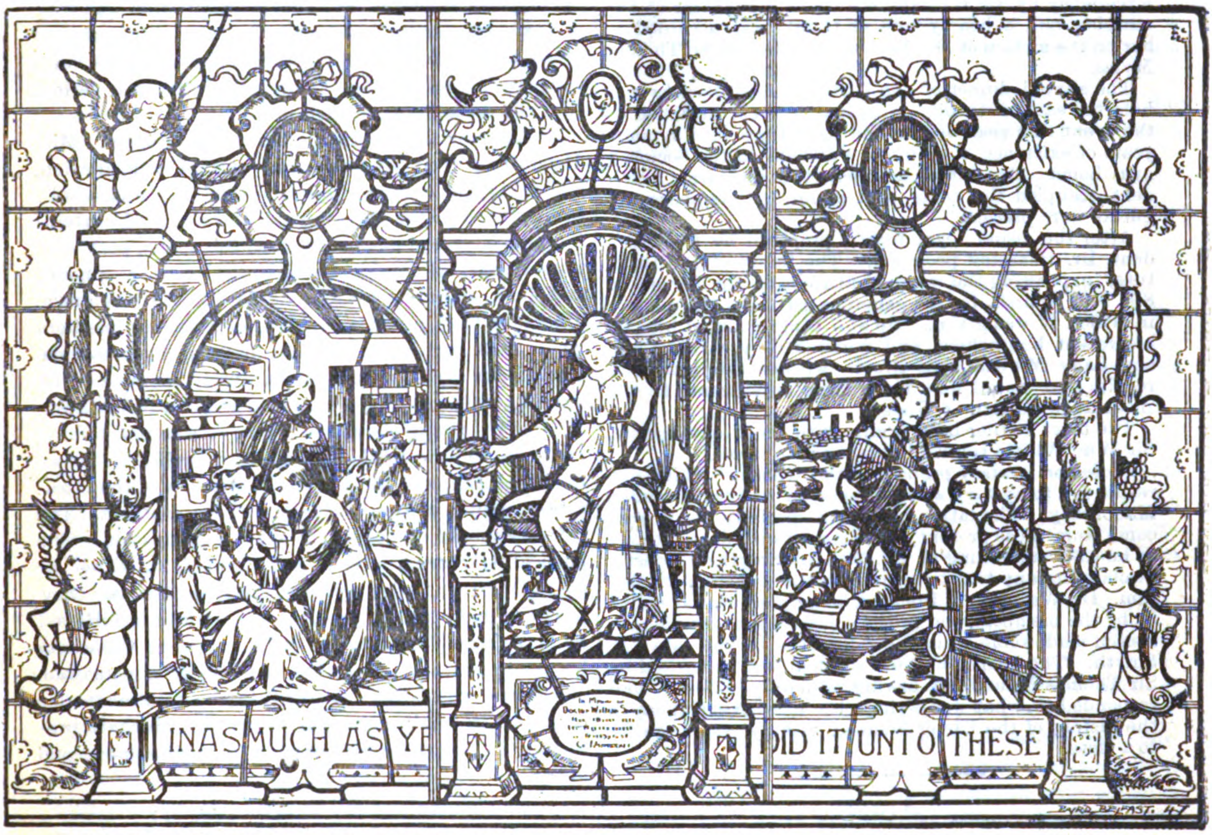
Sir William Quartus Ewart seconded this vote, saying, as a civilian and Belfast citizen, that anyone who conferred a benefit on medical science conferred a benefit on the whole community.

The vote was passed enthusiastically, and Sir William Whitla briefly replied.

At three o'clock on Wednesday afternoon a large gathering, consisting chiefly of the wives of medical men, assembled in the library of the new Medical Institute to witness the unveiling of the memorial window to the late Dr William Smyth by her Excellency the Countess of Dudley.

(a) Special report for The Medical Press and Circular.

The beautiful stained glass window commemorates the tragic and heroic death of Dr. Wm. Smyth, who, as all readers of The Medical Press will remember, died in November, 1901, of typhus contracted while assisting the fever-stricken inhabitants of Arranmore, co. Donegal.



THE SMYTH MEMORIAL WINDOW IN THE NEW MEDICAL INSTITUTE IN BELFAST.

The window is about 6 ft. long and 3 ft. high, and the subjects are arranged in three upright panels held together in a framework of Renaissance architectural ornament executed in quiet tones of white, grey, and yellow. The panel to the left represents the interior of an Arranmore cottage, the sick fisherman reclining in the foreground, with Dr. Smyth kneeling at his side feeling his pulse. Behind are other fisherfolk and a donkey and goat—a characteristic touch.

The panel to the right shows the boat close to the landing place, Dr. Smyth holding a sick girl in his arms and Dr. Brendan McCarthy rowing, while one of the sick men bails the leaky old craft.

The centre panel contains a fine allegorical figure seated in an alcove, holding in one hand the victor's wreath, and in the other the martyr's palm. On cartouches over the side panels are portrait heads of Dr. Smyth and Dr. McCarthy. Under the central panel is a short memorial inscription commemorative of Dr. Smyth's self-sacrificing work, and across the base is inscribed the text, "Inasmuch as ye did it unto these."

On the arrival of her Excellency and suite, Sir William Whitla made a brief explanatory speech, saying that it was not from any personal feeling he had erected this window, as he had never been privileged even to meet Dr. Smyth, nor was it merely to perpetuate his memory, for "while the billows break on Arranmore" that can never die. But his idea had been, when planning this building, to symbolise in art some noble precept or example of our profession, and leave it as a help and encouragement to those coming after. It was placed over the chimney-piece of the library, with the building so planned that it must be always in view, ever preaching the solemn and eloquent though silent, sermon to the Institute, of love to our fellow-men, devotion to duty, and self-sacrifice.

Her Excellency, who was loudly applauded, said: It is only because I feel that it might perhaps seem somewhat disrespectful to the memory of him whom we desire to-day to honour were I to remain silent while I perform my task of unveiling this window, that I shall try to utter a few brief words. At the same time, I experience a profound diffidence in doing so because any words of mine must be altogether inadequate either to express the feeling which is uppermost in all your hearts or to be in any way worthy of the subject on which I desire to speak. The few striking facts connected with the life and death of Dr. William Smyth are well known to all of you—the years during which he treated the sick at Burton Port; the outbreak of typhus on Arranmore, where he nursed the fever-stricken islanders and rowed them in an open boat to the mainland; finally, his death from the infectious fever. The profession to which he belonged is one with which is associated a lengthy chronicle of noble deeds, many of them unostentatiously performed in the ordinary course of duty, often unrecorded and unacquainted with fame. Of this profession he was a worthy representative. He lived an uneventful life in the midst of the fisher folk, to whom he ministered during many years, and in whose service he died. He seemed to have attracted little attention during his life, and was to the end of it wholly unconscious of having performed any unusual act of heroism. He was what might be called an everyday hero. To the people among whom he lived and moved he was a familiar homely figure deeply beloved; but perhaps he did not appear even to them in due perspective. Death has before now made such as he loom larger in the eyes of those who failed before to see their true proportion. But surely it is at the tomb of such men that succeeding generations kindle the touch of heroism, of high ideals, and of devotion to duty. His life teaches many lessons, and his memory distils a pleasant fragrance. Upon it rests for ever the dignity of service and of sacrifice.

After her eloquent and touching speech Lady Dudley unveiled the window, which was well shown by a cluster of electric lights behind it, the room being darkened, and Sir William Whitla read a poem, written for the occasion by Professor Boas, of Queen's College, Belfast.

A silver album, containing a copy of the poem and a monochrome print of the window, was presented to her Excellency by Sir William Whitla as a souvenir of the occasion, and a hearty vote of thanks was accorded to her on the motion of Dr. Nelson, seconded by Sir Thomas Myles.

The annual dinner of the Ulster Medical Society was held the same evening. Unusual interest attached to the event this year, as, for the first time in its many years of existence, the dinner was held in the Society's own home. Dr. John Campbell, the incoming President, occupied the chair, and about 100 members and guests were present.

After the usual loyal toasts, proposed by the President, Dr. Dempsey proposed, "The Donor of the Institute," expressing the warm gratitude of the Society to Sir Wm. Whitla for his generous gift, and the manner in which it was given. He also congratulated him on his recent knighthood, and concluded by wishing him and Lady Whitla long life to witness the beneficial results that would flow from their munificence to the medical profession of Ulster.

The toast having been drunk with great enthusiasm, Sir Wm. Whitla replied in appropriate terms.

Professor Lindsay proposed "the Guests," which was responded to by Sir James Henderson and Dr. Brendan MacCarthy. The latter received a specially warm welcome from those present, who listened with deep interest as he told something of Dr. William Smyths' modesty disclaiming any title to a share in the honour accorded him. Dr. Warnock, of Donegal, being present, was called on by the members, and in the course of a most felicitous speech made some touching references to the late Dr. Smyth. The health of the President was proposed by Sir Thomas Myles, and having been duly honoured and responded to, what was perhaps the most eventful day in the history of the Ulster Medical Society was brought to a close.

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, Dec. 7th, 1902.

Treatment of Arterio-Sclerosis.

Professor Huchard, the highly-esteemed therapeutist, whose treatise on heart disease and affections of the arteries is considered as one of the best of the standard works on the subject, wrote recently on the malady known as arterio-sclerosis, which he said was one of the commonest affections, since it was a malady from which nearly every person suffered sooner or later, being the inevitable consequence of advancing years. Its study was very important, as it was against its progressive invasion and its effects that man had to struggle. The causes of arterio-sclerosis might be divided into two groups, the certain and the doubtful.

The certain causes were: Gout, diabetes, alimentary toxines, plumbism, arthritis, chronic rheumatism, heredity and senility. Doubtful causes: Alcoholism, tobacco poisoning, syphilis and mental overstrain.

The localisation of the malady depended on the cause; gout, arthritis, diabetes, affected the heart, aorta, and renal arteries (very frequent); chronic rheumatism, the arteries in general, but rarely the heart; heredity, endoarteritis; tobacco, probably the coronary artery; alcoholism, hepatic and pulmonary arteritis: plumbism, renal and cardiac arteritis; alimentation, general arterio-sclerosis (very frequent); senility arterial atheroma.

These indications were important, as they rendered possible the diagnosis of the malady at an early stage, when there was some chance of fighting against its baneful effects. Preventive measures consisted in introducing into the economy the least possible quantity of toxic substances and facilitating the elimination of those already formed. The application of those rules comprised nearly all the treatment of the first period, that of arterial hypertension.

Treatment: Hygiene and alimentary regimen. Milk diet should form an important part of alimentation, while certain exciting liquids should be suppressed; tea, coffee, liqueurs of every kind, and also food containing more or less ptomaines, such as fish, game, pork, and tinned meat. All liquids should be moderate in amount and just sufficient for the needs of the organism, otherwise they produce a kind of vascular plethora which was certain to provoke arterial hypertension. That strict *régime* should be absolutely imposed on all patients suffering from a gouty or rheumatic diathesis. While prescribing the above *régime* it was well to have recourse to intestinal antiseptics; naphthol, benzonaphthol, charcoal, but the best antisepsis of the intestine consisted in the evacuation of its contents. The patients should consequently avoid constipation. The medical treatment proper was limited to three or four drugs, but they rendered good service, as they produced more or less rapidly vaso-dilatation, followed by lowering of the arterial tension. Among these may be mentioned nitro-glycerine and iodide of potassium or sodium, the latter constituting the treatment *par excellence* in small continued doses. M. Huchard prescribes the following preparation as antidyspnœic and diuretic:

Tincture of grindelia robusta, ℥j;
Tincture of convallaria majalis, ʒijss;
Tincture of squills, ʒj.

Fifteen drops three times a day in water.

Dyspnœa being one of the essential signs of arterio-sclerosis, especially that to which has been given the name of toxic dyspnœa, of alimentary origin, M. Huchard as soon as he perceives it, institutes the following *régime* during six months or a year.

1. For eight days absolute milk diet, three quarts daily.

2. During the following eight days (and so every month during the whole period) mixed diet; eggs, fruits, grapes, small quantity meal once a day and never in the evening.

3. Suppression of game, cheese, tea, alcohol, tobacco.

4. A slight purgative now and again.

5. During the period of mixed diet two or three wafers of ten grains of theobromine.

6. During the period of purely milk diet iodide of potassium.

7. In case of cardiac insufficiency moderate doses of digitalis.

Incontinence of Urine.

The following will be found an effectual remedy for this distressing complaint:—

Tincture of rhus aromatica ... ... ʒj.

Fifteen drops twice a day for a child ten years old.

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, December 6th, 1902.

Malignant Growths in the Thyroid.

Hirsch, at the "Gesellschaft der Aerzte," related the history of a young man, æt. 19, who was received into Professor Mosetig's ward on September 29th last. His own story was that two years ago he noticed that his neck was getting very small and he had been told that his thyroid gland was disappearing. This had gradually continued till within six days before admission when a rapid enlargement of the neck set in, causing him difficulty in swallowing and breathing. His voice gradually became hoarse, with frequent attacks of pain in the back of the head.

On examination a tumour was found in the neck over the site of the thyroid about the size of a man's fist, with a peculiar consistence of hard and soft prominences, although otherwise it might be described as elastic or pseudo-fluctuant in character.

The laryngoscope revealed a paralysis of the right recurrent laryngeal nerve, with dislocation of the trachea towards the left, giving it a curved shape.

The diagnosis, notwithstanding the complicated symptoms, was given as a sarcoma of the thyroid. The rapid growth and irregular consistence favoured this opinion.

On October 1st, under the influence of Schleich's local anæsthesia, the tumour was extirpated as a radical cure, although the danger from strumoderma was equally great. The tumour was very easily enucleated, except at one point on the right side where it had become attached to the cartilage of the larynx.

The pathological examination of tumour under the microscope proved it to be a carcinomatous adenoma. On October 10th the stitches were removed. On October 14th, *i.e.*, a fortnight after the operation, when the larynx was examined, a small tumour about the size of an apple was observed on the right side. A few days later a similar enlargement occurred on the left side, which was evidently a recurrence of the original.

These two tumours increased in size, rapidly covering the whole of the front and sides of the neck right back to the spine. A few days later tracheotomy had to be performed owing to the occurrence of alarming dyspnœa, but during the operation the trachea could not be found owing to the great shrinkage and displacement behind the tumour, and the patient died forty minutes later from suffocation.

The important points to be noted in this case were (*a*), the occurrence of carcinoma in so young a subject; (*b*), the rapidity of growth, both of the original tumour and of the recurrent growths, notwithstanding the early extirpation of the neoplasm which was supposed to be completely removed; (*c*), the failure to carry through the operation of tracheotomy.

The pathological preparations were examined to discover the cause of failure in operating, and the trachea was found to be greatly contracted and stenosed, while the cartilages were quite soft and flexible. The growth involved the jugular veins and their branches. Metastatic deposits were discovered in the pleura and lungs.

Facial Hemiatrophia and Paraffin.

Schlesinger showed a case of hemiatrophy of the face, which he had treated with subcutaneous injections of paraffin, with the best results.

Dwarf.

Kienböck showed a youth about eighteen years of age, who was 113 centimetres high (34 ins.), whose limbs were in proportion to the height. He presented an infantile appearance, and the mind decidedly pseudo-psychical—no hair about face, axilla, &c.; no cretinism nor inclination to myxœdema; on the contrary, he is fat and well nourished. All the rest of the family are healthy, the thyroid gland being normal in size.

The Röntgen rays showed the skeleton to be in due proportion, though slender, and resembling ossification in the eleventh year.

Kienböck is of opinion that this was a form of semi-cretinism with simple proportions, with stunted growth both corporeal and psychical.

Injurious Effects of Atropin in Ileus.

Atropin, when used for any length of time, has an injurious effect on the nervous system, particularly the vagus and splanchnic nerves, while the muscles of the bowel and the ganglia which serve the peristaltic motion remain almost unaffected in structure by its use. Again, atropin in its action acts most potently on the bowel through inhibitory nerves such as the splanchnic, which may often give rise to more trouble than benefit to the patient as the peristaltic action becomes more vigorous and the patient more sensitive. When small doses of morphia are combined the effect is marvellous in cases of ilius.

The rational application of atropin would be where the ileus itself is paralysed, or almost so, when the action of atropin would be beneficial in relieving the inhibitory apparatus and thus getting rid of much of the paralysis.

The atropin theory for ileus is fallacious and misleading, as it is only in very complex conditions that it can succeed, although its combination with opium or codeia may prove to be of the utmost benefit to the patient, but alone may cloud and confuse the whole symptomatology of the case.

THE CANARIES AND MADEIRA IN WINTER.

[FROM OUR SPECIAL CORRESPONDENT.]

The Voyage.—Liverpool was in a melancholy mood when the ss. "Fantee" sailed for the Canaries last month; King Boreas was, in truth,

"Monarch of all he surveyed;
His right there was none to dispute;
From the centre all round to the sea":

so far, indeed, seemed his territory to extend that the captain thought it prudent to cast anchor in Holyhead Bay and allow his fury to exhaust itself. Sunday, as befitted the day, a comparative restfulness succeeded; rain had ceased to batter the face of the hardened steersman, and we started afresh and landed at Las Palmas on the following Saturday without further hindrance by the elements. After the first two days we left behind us the cold and gloom of November—so unfortunately natural to our northern climate—and as we neared the sunny south, overcoats and wraps of all kinds were dispensed with and one could lounge or pace the deck in ordinary summer attire. Our ship "Fantee," one of the recent additions to the magnificent fleet of the Elder, Dempster line (African Royal Steamship Company), whether viewed in her sea-going qualities, her design for the comfort and health of passengers or the politeness and attention of her officers and staff, left nothing to be desired, while a liberal table with an abundance of fruit at every meal ministered to the necessities of the robust, whose seaboard appetites probably surprised no one more than their owners. To those, however, who are not good sailors it must not be denied that a week's sea passage will always act as a deterrent even with the charming winter climate of the Canaries in prospect; but go where we will out of this sea-girt isle of ours, a shorter or longer voyage has to be got through, and to those who have the courage to face one of this length, no finer health giving tonic can be prescribed, the transient miseries of *mal de mer* are soon forgotten on touching shores bathed in sunshine and alive with novel associations. The ship having for its destination Sierra Leone, Bonny, and other British possessions along the West African Coast carried an unusually interesting living freight; many in the upper ranks of coloured natives were returning from England after completing an English education in preparation for Government posts. Dr. Manley was going on an official mission to Bonny and the Nigerian territory, and several other members of the medical profession were returning to duty or to fresh Government appointments. "Doctors!" exclaimed the steward on inquiry, "well, sir, if all the passengers and ship's crew were taken ill, there would always be plenty of doctors on this line to look after them."

The Canaries.—Having arrived at Las Palmas, the capital of Grand Canary and the port of call for most of the ships to and from the Cape, the West Indies, and West Coast of Africa, the visitor at once becomes impressed with the distinctly Eastern character of his surroundings. Hordes of swarthy men and boys surround the vessel in small craft, offering for sale the fruits, lace, and other goods of the island, tunics of rainbow hues from Morocco and neighbouring coasts, cigars and tobacco at ridiculously low prices. At Las Palmas there are two principal hotels—the Catalina and the Métropôle. Most of those on board went to the latter, it being, like the ship, under the control of Messrs. Elder, Dempster and Co., and a very excellently-managed hotel at moderate charges we found it. Of modern construction, it is well drained, lighted by electricity throughout, and, being built literally on the sea beach, cool sea breezes temper the heat even when the sun is hottest. It may be urged that too much attention should not be paid to one personal experience. I may have been more fortunate than others, but during the fortnight I stayed in the Canaries I saw neither rain nor fog, open sea bathing was indulged in every morning, and this in the latter end of November, with the mean daily average temperature in the shade of 65° F. For the invalid or the overworked City man of whatever profession I can imagine no climate to be more of a paradise; there is no temptation to excitement, but rest absolute and complete under a canopy of ethereal blue, in a temperature which varies probably less than in any other part of the world. The Canaries are, however, distinctly disappointing in scenery, their volcanic origin is apparent everywhere. Yawning craters, acres of lava and inaccessible peaks meet one at every turn, and the roads are abominable. But when one comes across ground under cultivation, as in the Orotava, Monte, and La Palmas districts, orange groves, mangoes, date palms, figs, and bananas grow in luxuriant abundance, and form, as it were, delightful oases amid the desert of igneous rock, seismic cinders and sand. Of the inhabitants little need be said; poverty is everywhere apparent, and the troops of children who greet you at every turn lead one to imagine that the tenets of Malthus have not penetrated herein. They are an industrious, apparently happy and contented race, drunkenness being almost unknown. English physicians are resident both at Teneriffe and Grand Canary, so that practitioners desirous of information before sending patients may be reassured on this point.

To anyone anxious for a mountain climb there is the majestic Peak of Teneriffe, nearly 13,000 feet in altitude, which can be seen towering above the clouds a hundred miles distant, whilst golf links are provided for those in need of this kind of exercise.

Of the cost, I know of no holiday that can be obtained at so great a distance for so little money. The shipping company before mentioned issue special tickets for a month (and it was with one of these I travelled) for £15, which includes passage and board on the steamer both ways, and board and residence at the Hotel Métropôle, Grand Canary, for the intervening fortnight, so that with £5 thrown in for wine, excursions to the islands and incidental expenses, the whole can be accomplished comfortably for £20.

I propose devoting a few lines next week to the Island of Madeira.

The Operating Theatres.

GUY'S HOSPITAL.

Removal of Half the Lower Jaw, the Inside of the Cheek, the Tonsil, part of Soft Palate, and of the Tongue.—Mr. Clement Lucas operated on a man, æt. 51, who had been admitted for a swelling of the cheek on the right side. The patient's family history was good, and he had never suffered from any illness. About eight months ago he got very weak and began to lose his appetite; some lumps appeared under his chin and down the side of his neck; two months later he had severe toothache in his right lower first molar, and then a lump developed in his cheek just opposite the offending tooth; this last was extracted, but the lump remained and had since then been growing, giving little or no pain; the glands in the neck were at times swollen. During the eight months the man had lost about three stones in weight. At the time of the operation there was a swelling in the cheek extending on the outside from the angle of the jaw forwards for about two and a-half inches, and measuring about one inch and a half from above downwards. It was quite hard and fixed, and caused no pain on manipulation. Inside the mouth, as far as it was possible to determine, there was a hard swelling, which extended from the anterior pillar of the fauces forward as far as the canine tooth; the teeth behind the canine had been extracted and the gums appeared to be involved. Glands could also be felt in the neck. The odour from the mouth was very fœtid. A.C.E. and then ether were first administered until the patient was fully anæsthetised, a nasal tube with chloroform being used for the latter part of the operation. A Gower's gag was put in the left side of the mouth and a large hook extractor was employed to retract the cheek on the side of the growth, the extent of which was now evident. It involved the ramus of the lower jaw, having absorbed the bone and gum tissues under the masseter muscle, forming a large excavated ulcer on the inside of the right cheek; backwards it implicated the whole of the tonsil and soft palate to within a quarter of an inch of the uvula; it also extended on to the side of the tongue, forming a deep pocket between that organ and the tonsil in which food had collected and decomposed. Mr. Lucas ran a knife from the angle of the mouth on the outside to the angle of the jaw, cutting through the skin and superficial structures and dividing the facial artery and vein, but not the mucous membrane, so that no blood got into the mouth; he next carried a curved incision from near the symphysis along the body of the jaw and up behind the ramus, and dissected out some glands; on the flap being dissected back, the jaw exposed, and the mucous membrane divided, it was evident that the growth had absorbed the whole of the ramus excepting the two processes. The dissection was then carried up to the level of the zygoma, and the masseter was detached; the coronoid was next exposed, and the temporal muscle detached from it; the condylar process, being above the level of the growth, was snipped through with cutting forceps. The growth having been cleared on its under aspect, the side of the tongue was cut off with scissors and the soft palate divided just on the right of the uvula, and these parts, together with the tonsil and intervening tissues, dissected outwards. Finally, the palatal muscles and the internal pterygoid having been divided, together with the third division of the fifth nerve, the whole mass was removed. The surface of the wound was powdered over with a mixture of tannin and iodoform, and plugged with iodoform gauze; the wound in the cheek was sewn up, a small gauze drain being left in at one angle. Mr. Lucas said that the patient being in a very cachectic condition from advanced malignant growth, the operation was undertaken to get rid of a foul tumour and to prolong life. The character of the growth, however, would have to be determined by microscopical examination. He thought the extensive ulceration involving the cheek, the tonsil, the palate, and the side of the tongue had the appearance of epithelioma, but the history of prolonged toothache and swelling about the jaw rather seemed to indicate a growth commencing in the bone ulcerating internally, and spreading from that point. In whichever direction the growth spread, whether from inside towards the jaw or from the jaw towards the palate it had absorbed the ramus of the jaw, in its course. He pointed out that the man had an advanced calcareous condition of his arteries, and had been for some years subject to angina when walking up hills, which gave great anxiety lest his heart should fail under an anæsthetic. Mr. Lucas therefore had communicated with two of the special anæsthetists of the hospital to administer in this case, but neither was available, so Mr. Gray, the house surgeon, as usual gave the anæsthetic. The patient, Mr. Lucas remarked, bore the operation fairly well, but once or twice his respiration became impeded and his pulse very low. Great care had been taken to allow no blood to pass into the trachea. Mr. Lucas drew attention to the incision from the angle of the mouth to the angle of the jaw, and the curved incision round the margin of the jaw, which enabled him to leave the whole of the skin over the tumour, and also gave a very clear view of the parts that he wished to remove. Besides, when the whole of the extensive growth had been removed and the incisions brought together there was from the outside very little appearance of injury, the face being left intact. The patient recovered well from the immediate effects of the operation.

Registered for Transmission Abroad.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5 0s. 0d.; Half Page £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 10, 1902.

PATHOLOGICAL EVIDENCE AT INQUESTS.

It has long been evident that some modification of the present plan of obtaining pathological evidence at inquests is necessary. But too often the course of justice has been thwarted or deviated by the inadequacy or inaccuracy of the evidence based on the results of a post-mortem examination made by one who has had no special training for the task. It is obvious that pathological investigation requires considerable training and experience; it is a special branch of medical science—as distinctly a speciality as ophthalmic or lunacy work. To entrust this responsible task to any but an expert is to run the risk of vitiating the evidence based on the results obtained. In the country, it is true, it may still be necessary for the Coroner to avail himself of such assistance as may be obtainable, but the time is probably not far distant when every County Council will appoint its own pathologist, one of, whose duties will be to perform or superintend the making of post-mortem examinations for medico-legal purposes. This recognised, it will be usual, in cases of special interest or notoriety, for him to secure the assistance of a skilled pathologist when it falls to his lot to have to make the necessary examination. We have, on more than one occasion, in commenting on the shortcomings of the present system, urged upon the authorities the desirability of entrusting the making of these delicate medico-legal inquiries to medical men whose special training and experience ensure the examination being complete and conclusive. The London County Council, in an unostentatious way, has apparently arrived at a similar conclusion, for a gentleman has recently acquired the right to describe himself as pathologist to that body. Some adverse comment has been excited by this gentleman's appearance on the scene, several of the metropolitan coroners having departed from the usual course of entrusting the post-mortem examination to the practitioner who happened to have been called to the person whose death is the subject of inquiry, and having delegated that function to the gentleman in question. While we willingly acquiesce in the principle involved, this appointment is enveloped in too much obscurity for it to meet with cordial endorsement. The appointment is one of considerable moment, and embodies an innovation of very far-reaching importance. It is odd, therefore, to have it sprung upon us in this almost surreptitious fashion, and the lack of consideration shown for the profession at large in this abrupt departure may conceivably lead to much undesirable friction in the near future. As if to render this inevitable, the services of "the pathologist to the London County Council" have actually been requisitioned for the purpose of pathological examination on persons who have died in two at least of our large general hospitals, where assuredly there is no lack of persons perfectly capable of carrying out the investigation with the necessary skill and ability. There is no question, we imagine, as to the right of the coroner to confide the making of post-mortem examinations to whomsoever he, in the exercise of his discretion, thinks fit, and, in a general way, the practice of employing a person specially qualified for the task will commend itself both to the public and to the profession. To do so in the case of hospital patients, however, appears to be a wanton imputation on the skill or the trustworthiness of the hospital pathologists, and this is certain to be resented. Moreover, such services have to be paid for, and although, somehow, we are ignorant of the details of the arrangement, it may reasonably be assumed that an additional and unnecessary burden will thus be laid on the ratepayer in connection with inquests on hospital patients. The coroners are the paid servants of the London County Council, although they derive their authority from the Crown, and they are doubtless acting on instructions received from headquarters. This may explain how it is that it has not been thought necessary to invite the co-operation of the representative bodies of the profession to assist in drawing up a scheme to carry out the principle involved in this new departure, it being regarded as a purely administrative detail.

PUBLIC WATER SUPPLIES.

The water supply of any community is so closely connected with the public health that the medical profession is concerned with all that tends to raise the cost of that prime necessity of life or to lower its efficiency, either in quantity or in quality. We feel convinced that all the bad points mentioned are comprised in Mr. Long's Bill now before Parliament, and we therefore call the attention of our medical readers in all parts of the Empire to what is now being done in London. What the monopolists are effecting here to-day the monopolists will attempt elsewhere to-morrow, that is to say, in those towns and districts that have not been wise enough to secure a water supply of their own. The Metropolis has been handed over to a number of rival companies that have for many years drawn large profits out of the sale of water to the citizens, and in this way have established an enormous capital value as regards those undertakings. For some time past proposals for the purchase of the properties of the water companies have been laid before Parliament, and in consequence the value of the companies' stock has been inflated to an inordinate extent, always at the cost of the ratepayers. Several Purchase Bills introduced by the present Government have fallen through. They have all been characterised by features more or less antagonistic to the interests of the consumer. The average water company, being in possession of a monopoly, can make its own charge for the commodity it sells, and may or may not, as it thinks fit, give in return good water, sufficient in quantity and pressure, constant in supply, and conveyed in properly-laid and maintained distributing pipes. Failure on their part practically escapes any penalty, as witness the whitewashing of the wealthy corporation that year after year brought endless loss and suffering upon East Londoners by recurring water famines. The only way in which citizens are likely to have a good supply is by having that direct control over machinery which goes, or should go, with ownership. Mr. Long's Bill places the future control of the London supply after purchase in the hands of a huge nominated Board of sixty or seventy members. No body of that unwieldy size could possibly act in a prompt business-like way. The majority of its members will be nominated by the Borough Councils, and although they will almost certainly for the most part know nothing of the complicated water question in the Metropolis, they will be nevertheless entrusted with the bargain to be concluded by the companies. The pith of the matter lies in the absence of direct popular control by election of the managers of Mr. Long's proposed water trust. Why should London be denied privileges that belong to every petty town in the kingdom? In Birmingham the water supply is administered by a small business-like committee of nine members. The water supply is owned by the citizens and the profits are diverted from the pockets of private shareholders to lessen the rates in other directions, and to cheapen the cost of water, while at the same time Birmingham is acquiring an enormously valuable property by the operation of a compulsory sinking fund. Why similar advantages should not be available for the Metropolis is a mystery, the key to which lies hidden in the hearts of his Majesty's governors and their supporters. As a former director of a London water company, Mr. Long, the author of the present preposterous scheme, must be thoroughly acquainted with the wants and the wishes of Londoners upon the whole question. Possibly it is that very knowledge which has convinced him of the hopeless apathy of the average Metropolitan ratepayer when called upon to protect his vital interests. However, there is some prospect that he may summon enough interest at the next Borough Council election to register his views at the poll on the Board Schools and the water supply that in future he will support but not control. So far as the water supply is concerned it should offer matter for deep and earnest meditation to every citizen in the United Kingdom, more especially if his lot be cast in places where the leaven of municipal reform has not yet penetrated.

Notes on Current Topics.

The General Medical Council.

The Council during the session which terminated on Tuesday last disposed of a certain number of questions by postponing them. It is obvious that members are not disposed, without further consideration, to pass anything of the nature of a self-denying ordinance, and they display much greater willingness to discuss means of adding to the income of the Council than of measures whereby economies might be effected. We believe this feeling will be reflected in the profession, that is to say, practitioners as a whole are less concerned to dock members' fees or to cut down expenses than to possess a Council that does its work efficiently. An increase in the fee for registration which is paid once and for all may excite a passing grumble, but it is scarcely likely to arouse opposition, especially as those who will be called upon to pay it are not yet actual members of the profession and have therefore no *locus standi*. It is certainly an excellent thing to clear up the ambiguity which at present qualifies the right of the Council to insist upon the registration of medical students, and it is not unreasonable that a fee should be paid for the privilege of registration, unasked though it be. One plan for diminishing the expenses of the Council, which does not appear to have had even the empty honour of a mention, is a reduction in the number of members by fusion of corporate representation. Perhaps the British Medical Association, or some kindred body, might induce a friendly member of Parliament to introduce an amendment to that effect at the opportune moment, and, even as matters stand, it is open to anyone, when the Privy Council is approached, to make this suggestion as an alternative to the proposals emanating from the Council. No mention is made in the draft Bill of any provision for the simplification of the procedure in penal cases, although this was mentioned as one means whereby an immense saving of time, and therefore money, might be effected. Yet, as the procedure is ordained by statute, it is presumably not open to the Council to modify it without legislative sanction. The most characteristic feature of the discussions on the subjects raised by the draft Bill is the manifest insincerity of many of the speakers. They talk in an airy sort of way of doing this or that, but when it comes to the test of the vote it is by no means sure that even the most ardent advocates of economy would support a motion for reducing expenses with their votes.

Milk Analysis at Somerset House.

The prevention of food adulteration is of such prime importance to the community that it is absolutely essential that official analyses should be scientific in method and as nearly perfect as may be humanly possible. So far as milk is concerned, discontent has long been freely expressed with the methods of analysis followed at Somerset House, the Court of Appeal, so to speak, of milk prosecutions all over the country. It becomes a somewhat serious matter, therefore, when public analysts come forward and denounce the methods in vogue at Somerset House as antiquated and untrustworthy. Mr. Cassal, the well-known analyst, agrees with other authorities in this condemnation. The chief grounds appear to be, first, that a specimen sent to Somerset House may not be examined for a month or six weeks after being taken from the vendor. Obviously, decomposition and evaporation may by that time have so seriously changed the original composition of the milk as to render its nature a matter of guesswork. Somerset House, indeed, arrives at its verdict by allowances for disturbance by decomposition and other agencies. The science of analytical chemistry, however, is exact, and the results of half-a-dozen separate analyses of a given sample of milk should not vary more than by a fractional margin of difference. As things go, however, Somerset House often contradicts public analysts, who, for all that, are more likely to be right, inasmuch as they are ready to state their methods, and they are many in number. Meanwhile the public suffers and fraudulent milksellers flourish. It is to be hoped that some member of Parliament will take up the matter.

The Treatment of Dysmenorrhœa.

Dysmenorrhœa is such a protean affection that it seems to defy classification, and its treatment is consequently vague and uncertain. Its relationship to uterine disease and displacement is the subject of perennial discussion, and it cannot be said to have any pathology of its own. Roughly speaking, cases of dysmenorrhœa may be divided into two classes—the cases in which the pain, once established, is constant, and those in which it is spasmodic or intermittent. Constant pain is believed by some to be indicative of ovarian origin, while the intermittent form is associated with functional distress of the uterus. In the latter form the onset of the pain coincides with the onset of menstruation, and in these cases dilatation of the cervix is often followed by marked relief. The objection to dilatation of the cervix is that the relief which it affords is almost of necessity ephemeral, and in order to render it permanent certain gynæcologists advocate division of the circular muscular fibres of the cervix. It is to be feared, however, that this operation, though it may relieve the dysmenorrhœa, exposes the patient to the usual consequences of laceration of the cervix—consequences which the operation of trachelorhaphy was specially designed to obviate. Restricting the purpose of our remarks to the treatment of dysmenorrhœa of uterine origin, in which the pain comes on with the flow; is more or less intermittent in character and is not relieved by lying down; dilatation of the cervix will afford relief in a considerable proportion. Dilatation does not correspond to any particular size of sound; the essential thing is to introduce larger sizes until resistance has been overcome.

The Disposal of the Dead.

The aggregation of mankind in towns and cities has made the problem of the disposal of the dead one of pressing importance to the living. Undoubtedly cremation affords the safest and most rational means, and slowly but surely prejudices are being overcome. As evidence, we have the opening recently, by Sir Henry Thompson, the apostle of fire as he has very aptly been termed, of a new crematorium at Golder's Green, overlooking the Finchley Road, and in curious juxtaposition to the Jewish cemetery. The method of disposing of the dead by cremation is hygienic, simple, expeditious, reverential, economical, and free from painful incidents. The practice of cremation is undoubtedly advancing. Crematoria have been built at Manchester, Liverpool, Glasgow, Hull, Darlington, Birmingham, and one is now being erected at Leicester. There were 445 cremations in this country last year. But America, of course, is in advance of us, for the United States possess 25 crematoria, where last year 3,613 human bodies were reduced to ashes. Germany has seven crematoria, Italy 22, Switzerland three, and Sweden and Denmark one each. It should be remembered that the Act enabling public authorities to erect crematoria will come into force on April 1st, 1903, and a Home Office Committee is now considering the framing of definite rules whereby all fear of cremation being used to conceal crime may be absolutely avoided.

Bacteriæmia.

An interesting series of bacteriological experiments on the blood of typhoid fever patients has just been concluded at Munich by Schottmüller. He finds that the bacilli of typhoid fever may be cultivated from the blood of the patient in 75 per cent. of the cases, and that the earlier in the disease the examination is made the greater their frequency. He has cultivated the bacilli from the blood as early as the second day of the fever. From experiments on almost 200 cases he found that the bacilli were proportionate to the amount of the fever. When the temperature was at its highest the bacilli were both numerous and active, and on the subsidence of the pyrexia they were no longer to be detected. His technique is different from that formerly employed, in that he draws the blood directly from the patient's vein, and in much larger quantities than formerly, which he catches in melted agar at a temperature of 115° F., which is then poured into plates When it is considered desirable to produce colonies of bacteria, he further dilutes the blood in the proportion of one in three. These experiments, which are numerous and carefully conducted, revolutionise our theories of typhoid fever and place in our hands not alone a diagnostic sign so characteristic of the disease as to eliminate doubt, but it likewise gives us a prognostic sign of the greatest value. That typhoid fever might run its course without producing any intestinal lesion has often been demonstrated, but until Schottmüller's experiments made clear that the disease is a bacteriæmia there was no intelligible explanation of the fact; neither could it be understood why the intestinal lesions were not proportionate to the clinical features of the case. The bacilli probably enter the blood both by the alimentary canal and by the respiratory tract, the familiar intestinal lesions being of hæmatogenous origin. If this theory of typhoid fever is accepted, more reliance will be placed on the antipyrexial properties of water, as a bath and as a local application by sponging, and less on intestinal antiseptics. The theory further holds out the hope that the preparation of a preventive anti-typhoid serum is only a matter of time.

The Legislative Repression of Leprosy.

In a recent number of the *Polyclinic* the view that leprosy can be suppressed by legislative enactment is eloquently combatted. The author, Mr. Jonathan Hutchinson, bases his argument on the fact that although leprosy has disappeared from many countries in which it was formerly endemic, the improvement was not the result of repressive measures, but of gradually altered conditions of life. The Norwegian peasants, who in their native land still suffer from the disease, cease to be amenable thereto when they emigrate, and the prevalence of the disease at home is steadily decreasing owing to the better nutrition of the inhabitants since Norway has become the annual resort of multitudes of tourists whose money enables them to improve their dietary. It is possible also that the objection which tourists manifest to fish not quite fresh may in the long run have excited a feeling of distrust among them in regard to this national delicacy. In view of the hardship and misery of compulsory segregation, resort to this drastic measure can only be justified by unquestionable evidence of its efficacy, and of its being the only alternative. Mr. Hutchison denies that it is the cause of the improvement, even when this has coincided with segregation, and he is firmly convinced that there are other and better means of checking the spread of the disease.

Board of Trade Testing for Colour-Blindness.

It is curious to learn at the present day, when the importance of detecting the existence of colour-blindness in those engaged in certain trades is so thoroughly appreciated that, in the opinion of some capable authorities on the subject, the methods of doing so adopted by the Board of Trade are not in all cases either correct or sufficient. At a recent meeting of the Ophthalmological Society, Dr. F. W. Eldridge-Green, in the course of a paper on the necessity for the use of colour names in a test for colour-blindness, stated that over 38 per cent. in one year and 42 per cent. in another year of the rejected candidates at a Board of Trade examination had been found to be wrongly rejected and to be normally sighted. Another statement made at the same time is of more practical importance. A wrongly-rejected candidate is an instance of the unmerited bad luck of a single individual, but a wrongly-passed candidate is a danger to the community, and apparently many candidates are so passed. Dr. Eldridge-Green divides colour-blindness into two distinct classes. In the first class he includes individuals who cannot see certain rays at one or other end of the spectrum, and who have in consequence a shortened spectrum—a class which has its analogue amongst aurally defective individuals in those who cannot hear very high or very low notes. The second class of the visually defective includes those who make mistakes, not because they cannot perceive a colour, but because they cannot recognise the differences between colours as normally sighted people are able to do; a failing which is an analogue to what is usually known as a "defective ear" in the case of those who are aurally affected. The practical importance of eliminating both these varieties of colour-blindness is obviously very great, and yet we learn that the Board of Trade tests make no provision for detecting the first class of cases. The serious nature of this is readily shown by the example brought forward by one of the speakers at the meeting of the Society. An engine-driver, who falls into the first class in consequence of a shortening of the red end of the spectrum, will declare that he sees no light in the case of a distant red light, although he may have been able to pick out successfully all the green wools in the classification test. If such a state of things exist—as from the report of the Ophthalmological Society we must believe it does—the danger to the travelling public both at sea and on land is very great, and the necessity for a revision of the stock tests of the Board of Trade is very obvious. An engine-driver or a sailor, when he sees a light, has to be able to quickly allocate it to one of three groups. To do so he has to ask himself whether the light he sees is white, green, or red, and this question once answered there is no necessity for particularising its exact shade. It seems to be radically wrong that at the present time tests should be applied to determine whether such a man can distinguish orange from yellow, or blue-green from yellow-green—matters with which, so far as his trade is concerned, he has nothing to do, and that at the same time no test should be applied to determine whether he possesses the power of seeing the full range of the spectrum. If a man is blind to white light, he comes into the category of the totally blind, and if a sailor or an engine-driver is blind to red light, he should, so far as his trade is concerned be placed in the same category.

Adrenalin.

This product, embodying the active principles of the suprarenal glands, was first obtained by Dr. Takamine, a Japanese chemist, two or three years ago, and a considerable body of evidence has since been published, establishing its value as a therapeutical agent. Its remarkable hæmostatic properties and its not less well-marked influence on cardiac innervation combine to render adrenalin an extremely interesting and potentially useful substance. According to a paragraph which went the round of the lay press, a few days since, Professor Poehl, of St. Petersburg, of "spermine" fame, has rediscovered this substance, but his claim to originality has since been repudiated by the St. Petersburg Pharmaceutical Association. The plan of "booming" a medicinal substance on the morrow of its introduction, before there can possibly have been time to investigate its therapeutic capabilities, is one to be unreservedly condemned, but in this particular instance the harm is not great, seeing that adrenalin dates back some years, and has already been carefully investigated by numerous observers in all parts of the world.

The Dangers of Drinking-Cups.

The Board of Education in Chicago has announced its intention of abolishing the use of drinking-cups in the public schools. This is a reform the necessity for which must have struck every intelligent person who has given the subject a thought. Anything more insanitary than the customary iron mug or similar vessel which is usually appended to a public drinking-fountain cannot well be imagined. A thirsty man suffering from a communicable disease of the lips uses the cup, and the next person wanting a drink sees the cup provided for him, and, without thinking of the consequences, drinks therefrom. Not only is the infection which has been left by a previous drinker still remaining on the cup, but, as if to avoid any chance of escape the edges of the latter are roughened from rust and bad usage, and so cause the necessary abrasions into which the poison is to be inoculated. Drinking-fountains are a necessity, but adjunctory cups are not. It ought to be an easy matter to so adjust the stream that, without any projecting nozzle to which the mouth could be applied, a gentle flow would be furnished which could be caught directly in the mouth, or, failing that, in the hands. Better to contaminate the water with one's own hands, however dirty, than to convey the dirt and possible infection of another person to the mouth. In these countries we are so radically opposed to doing for people what they ought to be able to do for themselves, that it may not strike the authorities that it is necessary to guard the public in the manner specified. The authorities say, and say truly, that there is no necessity for an intelligent person to use a drinking-cup if he does not consider it to be safe to do so. This is quite true, but still, even if the principle is applicable to adults, it does not apply to children, who are, perhaps, the most frequent users of drinking-fountains.

A New Test for Bile Pigments.

THE identification of bile pigments in the urine is a clinical detail of considerable importance. The reaction usually employed, that introduced by Gmelin, is open to the objection that on the addition of the acid to albuminous urine the precipitate of albumen obscures the play of colours. Moreover, should the urine under examination contain indican the resulting blue coloration, in association with the yellow tint of the urine, gives a green tinge calculated to mislead. Heller's reaction, on the other hand, is not very well marked, and entails the use of chloroform, which complicates the procedure. Dr. Baudouin, of Tours, has introduced a reaction which, from the point of view of simplicity and precision, appears to possess certain advantages over those in common use. He employs a solution of fuchsine (one-half per cent.). If two or three drops of the fuchsine solution be introduced into urine containing bile it immediately develops a fine orange tint, in marked contrast with the violet-red of the test solution. No other colouring matter of urine provokes this reaction, which is determined by very minute proportions of bile pigment.

Cancer in Scotland.

A VALUABLE contribution to the study of cancer has been recently made by Dr. W. G. Aitchison Robertson in the shape of a paper read before the Royal Society of Edinburgh. The writer has examined systematically the facts connected with deaths from cancer in Scotland over a certain period. His statistics tend to show that there has been of late years an increase in the disease, which causes no less than 7 per cent. of the total mortality in women over forty-five years of age. The mean average for the whole of Scotland from this cause is 4·13 per cent. Excluding the deaths of strangers, the apparently high mortality in Edinburgh, 5·15 per cent., was practically reduced to the normal. It is a curious fact that the towns display a relative healthiness as regards cancer when compared with country districts. A rigorous correction, moreover, raised most country districts to the normal, and in many cases to a point considerably above it. In Kincardineshire and Sutherlandshire the figures were brought from 4·02 to a good deal over the normal, while Haddingtonshire was raised from 4·25 to 5·59 per cent., and Peeblesshire from 4·68 to 5·07. The record for excessive cancer mortality came from Nairnshire, which, in its uncorrected state, stood at 8·77, but was afterwards increased by correction to 9·73. These facts present the local distribution of cancer in a striking and suggestive manner, and can hardly fail, sooner or later, to advance our knowledge of this mysterious scourge, which has hitherto baffled the curiosity of a host of scientific investigators. Turning to the practical deductions to be drawn from his painstaking analysis, Dr. Robertson is fain to be content with the statement of a series of negative conclusions. He was unable, for instance, to trace any relation between geological formations or dampness of soil and the cancer mortality of Scotland. He was also unable to find any evidence pointing to the rainfall in the various counties as contributing to the results, but stated that much more detailed local information was needed on that point. Neither could he find any connection between the amount and the character of food in any locality and the incidence of the disease. Dr. Robertson urged the importance of a combined investigation by medical men throughout Scotland, an excellent suggestion that, if carried out, would be of the utmost value in sifting and collating evidence with regard to one of the most obscure and deadly pathological conditions that afflict the community.

Well-to-do Hospital Patients.

THE abuse of the medical charities is a subject apparently of evergreen interest to all classes of journalism. This universality may be partly accounted for by the fact that in London alone something like three-fourths of the population receive hospital relief in the course of the year. The welfare or otherwise of the charitable institutions, therefore, claims the earnest attention of three out of four newspaper readers, who will naturally be pleased to hear of the legacies of benefactions and awards bestowed upon the particular hospitals that have secured their personal patronage. Neither hospital committees nor distributing funds give a moment's thought to the injury done to the medical profession, whose patients they are diverting wholesale by placing relief hospitals at the disposal of the well-to-do. To such an extent has the popular conscience become blunted that a few months ago a London newspaper published a prolonged correspondence arising from the expressed admiration of a contributor for the courage of a young lady with £300 a year, who, in spite of that income, did not hesitate to enter as a patient in the wards of a hospital. In hospitals like the London and Guy's, where money payments are taken from the very poor, the latter are thus actually contributing to the support in illness of persons who are well able to pay for medical care and attention. Supposing the lady above-mentioned went to a hospital where they were not above collecting the pence of poor patients, then she would be paid for in part by money squeezed out of the pockets of the labouring and indigent classes. From this point of view the ardour of the young lady's admirer might be somewhat cooled. Meanness is not prudence any more than bravado is independence.

Bullet Extractions and Nitrous Oxide.

The greater accuracy of modern surgery and surgical methods has done much to determine the localisation of bullets buried deep in the tissues of the body. The old porcelain-tipped probe of Nélaton, for instance, has been replaced by the electrical contact probe with electrophonic attachment. The actual extraction of bullets, however, stands very much as it did fifty years ago. The recent death of Mr. James Coxeter, at the age of ninety, recalls the famous instrument invented by him for the purpose, and largely used in the Crimean War. In the French War of 1870 nitrous oxide gas was largely used by army surgeons for the extraction of bullets and in other minor surgery. The introduction for that purpose was chiefly owing to the influenceof Dr. Evans, oculist at that time to the French Empress. Many of the cylinders thus used were obtained from Mr. Coxeter, who, in the year 1869, together with his son Samuel, founded the English industry of storing nitrous oxide gas in steel cylinders. The importance of that particular branch of business, as all the world knows, has increased to an enormous extent since its first introduction. The firm of Coxeter and Sons is one of the household names of the medical profession, with which it has been so long and honourably connected as the skilful inventors and manufacturers of instruments.

A Sanitary Crusader in the Pulpit.

During the present generation the gospel of sanitation has found considerable favour among members of the Church militant. The excellent work done in that direction by the Church of England has long been leavening the country, and the same may be said to a greater or lesser extent of almost all religious sects in the United Kingdom. Perhaps the most energetic protest ever made by a minister of the gospel in his official capacity was by the Rev. D. E. Jenkins, pastor of the English Presbyterian Church in the Welsh town which has earned the title of "Dirty Denbigh." Wearied out by the negligence and apathy of the Town Council on such elementary matters as the town sewerage, the reverend gentleman proceeded to rouse his fellow-citizens in the following pointed and dramatic manner:—He announced that on a certain Sunday he would hold a memorial service over thirteen children who had died of diphtheria in the town during the preceding nine months. In his subsequent sermon he attributed those deaths and the prevalence of diphtheria and of other zymotic diseases to the neglect of the Town Council, upon whom he bestowed a scathing denunciation. The course adopted by this practical reformer is worthy of all commendation. Religious teachers are far too apt to imagine that their duty begins and ends with the spiritual side of man's life, to the exclusion of his bodily welfare. It is to be hoped that Denbigh will lose much of its "dirtiness" under the purifying influence of this courageous minister's attack.

"Christian" Names.

One of the odd points discussed by the General Medical Council was the use of the term "Christian" names. Objection was taken to it on the ground that Jews, Indians, and others could not, properly speaking, be said to have any Christian names at all. Indeed, the description, strictly construed, would only apply to names conferred in baptism. Names such as John, James, Moses, Jacob, &c., might, however, be held to be Christian names, since they are drawn from Scripture, but then they are not likely to be affected by Hindoos, for instance. To provide an alternative description did not prove as easy as one might at first sight suppose, but after dismissing a long list of proposed substitutes the Council decided to ask for "names in full," which affords a very acceptable solution of the difficulty, if difficulty it be.

The Metropolitan Fire Brigade Service.

The efficiency and progressiveness of the Metropolitan Fire Brigade is a matter of first importance, inasmuch as it furnishes, or should furnish, an ideal standard for the guidance of the rest of the Kingdom. It is interesting, therefore, to learn that the London County Council is showing considerable activity in re-organising the local fire service of London. It is to be noted with satisfaction that since the Queen Victoria Street fire, last summer, a number of seventy-feet ladders have been added to the resources of the Brigade. At the same time it is to be regretted that an unjust attack upon Captain Wells by the Yellow Press should have resulted, to some extent, in the substitution of controversy for impartial investigation and reform. The London County Council, in its desire to shield Captain Wells, has published a report wherein the fire service of the Metropolis is made to figure as an ideal of perfection. The plain facts of the case, however, show that in broad daylight a number of persons were burnt to death in the heart of London simply because the firemen had not a ladder long enough to reach the top floor of an ordinary warehouse. Indeed, the County Council has since admitted the defects of its equipment by distributing long ladders in all directions, and by substituting new and up-to-date appliances and methods for former antiquated ways and means Watling Street station, which showed to so little advantage in the fatal fire, however, remains practically untouched. If the obstacle be the cost of a new site, the feasibility of covering in a portion of an adjacent railway cutting, as suggested some time ago by a medical correspondent, may be worthy the attention of the Council. We venture to suggest that the confidence of the public would have been more readily secured by an admission of error and a promise of amendment on the part of the Council.

Dr. A. E. Wright is about to resign his appointment as Professor of Pathology at the Army Medical School, and has accepted the post of Pathologist and Bacteriologist to St. Mary's Hospital.

It is now an open secret that the "Nobel Prize" in Medicine for the present year will be awarded to Major Ronald Ross, of the Liverpool School of Tropical Medicine. The value of this prize is about £8,000.

Major F. Heuston, R.A.M.C., C.M.G., Royal Hospital, Dublin, has intimated his intention of offering himself as candidate for the position of Vice-President of the Royal College of Surgeons in Ireland at the election to be held in June, 1903.

Dr. Andrew Balfour, of Edinburgh, goes out to the Soudan on Thursday to take control of the new chemical and bacteriological laboratories at Khartoum, which have been presented to the Government by Mr. Hy. S. Wellcome.

Literature.

MORRIS'S TREATISE ON HUMAN ANATOMY. (a)

This portly royal octavo of 1,328 pages presents a good account of our knowledge of the anatomy of the human body. The text is subdivided into eleven sections, and has been completely revised and, in great measure, re-written. There are but two of the eleven sections left as they stood in the second edition. These are Mr. Gunn's account of the anatomy of the eye, and Mr. Walsham's of the circulatory system—"Arteries, Veins, and Lymphatics." All the others have been corrected, expanded, and more fully illustrated. The number of illustrations has been increased by fifty-six, and some of the former ones have been further elucidated by the addition of colours. Much praise is due to the author and editor, for the care with which the various sections have been compared with one another by their respective writers. This is very necessary in case of a joint production like the present, where its omission would pretty surely lead to ugly discrepancies. A description of the "Skin" has been added by Mr. Anderson, and a very interesting and instructive account of "Vestigial and Abnormal Structures" has been contributed by Dr. Robinson. We consider the volume now before us to be probably the most trustworthy guide in the English language to the macroscopic anatomy of the human body.

L'ABBE ON THE BLOOD. (b)

This neatly got-up and clearly-printed booklet gives the reader an excellent summary of the present state of our knowledge of the composition, physical properties, and physiological functions of the "vital fluid." It is almost needless to tell those of our readers who are familiar with high-class French scientific literature, that its contents are placed before the discriminating inquirer in the characteristic style and diction of crystalline clearness which forms so distinguishing a feature of the productions of the "masters of science" of that gifted nation. The chapter on "Rupture de l'équilibre physiologique du sang dans les maladies" is most instructive—and suggestive. The amount of varied information contained in this small volume is far too great to make detailed criticism possible within the limits of a review. Besides, it is unnecessary. So we merely feel called on to recommend our readers to make themselves acquainted with its contents. The volume does the greatest credit to the powers and attainments of the author, as well as to the "elective affinity" of the eminent firm of publishers by whom it has been issued.

SCHAFER'S PRACTICAL PHYSIOLOGY. (a)

This little volume contains detailed directions for carrying out experiments in practical physiology such as are likely to be required by the medical student. The directions in question comprise only such elementary exercises as admit of being worked out by a large class. The work differs in this respect from most guides to practical physiology which are generally much more elaborate, and deal with problems which the average medical student cannot be expected to work out for himself. Diagrams of apparatus and reactions are given wherever necessary, and blank pages are supplied on which the student can record such additions or modifications as he may deem desirable. The name of the author is a sufficient guarantee of the quality of the teaching.

AN ATLAS OF ILLUSTRATIONS (b).

The volume before us consists of the first two fasciculi of a new Atlas of Illustrations in Clinical Medicine, Surgery, and Pathology, which is in process of being complied for the New Sydenham Society in continuation of the Atlas of Pathology. The present volume deals exhaustively with the subject of frambœsial syphilis, and consequently, though of the greatest interest and value to medical men who practise in the tropics, and to others who are specially interested in skin diseases, it does not possess quite the same attraction for the general practitioner that some of the later volumes of the series will present.

Fasciculus No. 1 contains a synopsis of our present knowledge of frambœsial syphilis by that well-known authority, Mr. Jonathan Hutchinson, and is illustrated by many beautiful photographic plates. Fasciculus No. 2 consists of illustrations of the disease in Ceylon, which are included under the term "parangi," with descriptive remarks by Sir W. Kynsey, C.M.G., F.R.C.P.I., whose official duties as Principal Chief Medical Officer and Inspector-General of Hospitals, Ceylon, has given him ample opportunities of studying the course of these maladies. The feature of the fasciculus is the beauty and excellence of the illustrations, which have been prepared from original water-colour drawings made by a native artist. The fasciculus as a whole is quite equal to anything of the kind the Society has ever published, and will, for a long time, hold the first place in the illustrated literature of the subject.

We congratulate the Society on the excellence of the first volume of the new series, and predict a most successful outcome for its new venture.

(a) "A Treatise on Human Anatomy, by Various Authors." Edited by Henry Morris, M.A. and M.B. Lond., Senior Surgeon to the Middlesex Hospital, &c. Third Edition, Revised and Enlarged. Illustrated by 846 woodcuts (of which 266 are in colours). London: J. and A. Churchill. 1902.

(b) "Le Sang (Physiologie Générale)." Par Marcel Labbé, Médecin des Hopitaux de Paris· Paris: J. B. Baillière et Fils. 1902.

(a) "Directions for Class Work in Practical Physiology." By E. A. Schafer, LL.D., F.R.S., Professor of Physiology in the University of Edinburgh, &c. Price 3s. net. London: Longmans, Green and Co.

(b) An Atlas of Illustrations of Clinical Medicine, Surgery, and Pathology. Compiled for the New Sydenham Society. (A Continuation of the "Atlas of Pathology.") Fasciculus XIV. (Double Number). Fasciculi I. and II. of New Series. Frambœsial Syphilis (Yaws and Parangi). With Descriptions by Jonathan Hutchinson, F.R.C.S., F.R.S., LL.D., and Sir William Kynsey, C.M.G., F.R.C.P.I. Plates A to H and LXXV.—XCI. Price to Non-members, £1 1s. London: The New Sydenham Society (agent, H. K. Lewis).

HYGIENE AND PUBLIC HEALTH. (a)

WE are not surprised to find a second edition of this book called for within a year of its publication. Based on Mr. Parkes' well-known handbook, the scope of which has been considerably enlarged and made more useful under the joint authorship, the present work should be found as acceptable to all students of hygiene as its progenitor. In view of the enormous increase in the subject matter to be dealt with in a modern treatise on hygiene, the authors have been well advised to omit, so far as possible, reference to analytical methods, which cannot be adequately discussed in a work of this size, and which, being of a practical nature, can be more efficiently acquired in the laboratory. While we have little fault to find with the majority of its pages, those chapters which deal with "Food" and "The Contagia" respectively, are, in our opinion, the most instructive.

A few statements are to be found here and there in the volume with which we cannot quite acquiesce. For example on page 232 the authors recommend the overhead extraction of the heavy dust associated with the metallic workers and grinders' trades. This is scientifically incorrect and against the usual practice, which, indeed, the authors themselves describe further on (page 291). Again, under the heading of "Compressed Air Illness," we read, "The rate of decompression certainly not to *exceed* one minute to every three pounds of pressure." We would substitute for "exceed" the words "be less than," and in doing so we believe our opinion is not contrary to that of those in a position to speak with authority on the subject. Whatever differences of opinion may exist as to the advantages of a prolonged "locking-out" process, no expert on the subject has, with the solitary exception of Foley, ever attributed any bad effects to it. Neither can we agree with the authors, in view of the existing laws, in fixing the marriageable age as "over fifteen years," nor in calculating marriage rates from such a datum.

These minor faults, however, do not detract from the general merit of the book, which is a genuine, and on the whole successful attempt to accomplish the increasingly difficult task of presenting to the student in a concise and readable form those numerous sciences comprised under the head of hygiene and public health.

OBITUARY.

DR. A. M. ALCOCK.

WE regret to announce the death of Dr. A. M. Alcock, medical officer of Innishannon dispensary district, which took place at his residence on the 27th ult. He was the son of the Rev. Edward Alcock, of Kilmeen Rectory. He became a licentiate of the Royal Colleges of Physicians and Surgeons in Ireland, and soon afterwards was elected medical officer of the Innishannon dispensary district, where he laboured for five-and-thirty years, winning the respect and confidence of his many patients, poor and rich, by his skill and courtesy; and their love by his unremitting attention to them in their sickness. Thus in harness and at a comparatively early age he died. A quiet, unobtrusive Christian physician.

Medical News.

Medical Sickness and Accident Society.

The usual monthly meeting of the executive Committee of the Medical Sickness, Annuity and Life Assurance Society was held on the 28th ult., at 429, Strand, London, W.C. There were present Dr. de Havilland Hall, in the chair, Dr. J. B. Ball, Dr. J. Pickett, Mr. J. Brindley James, Dr. M. Greenwood, Mr. F. S. Edwards, Dr. F. J. Allan, Dr. A. J. Rice-Oxley, Dr. F. S. Palmer, Mr. H. P. Symonds, Mr. Edward Bartlett, and Dr. Alfred Gubb. The committee were engaged in examining a large number both of current sickness claims and of proposals for membership. The claims show signs of slackening, and it is hoped that the total experience of 1902 will be found much more favourable than the accounts of the early months of the year led us to expect. On the other hand, the new business experience has been satisfactory all through the year, and notwithstanding that the committee have always declined to spend any part of the contributions of the members in paying commissions or for advertisements, the number of new entrants is steadily increasing. Prospectuses and all other particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London, W.C.

The International Congress at Madrid.

WE are requested by the National Committee for Great Britain and Ireland to announce that the South-Eastern and Chatham Railway have made the following arrangements for the issue of reduced fare tickets to members attending the Congress at Madrid next year:—1. Members can apply to Messrs. Cook and Son, Ludgate Circus, E.C. (sending them letter card of membership), and they will make all the necessary arrangements through to Madrid. 2. Members can act independently, and must in the first place send their card of membership to Mr. Sartiaux, Ingénieur en Chef de l'Exploitation, Chemins de Fer du Nord, Paris, for endorsement. On the return of the card they can obtain at Victoria or Charing Cross Station, on presentation of the card of membership, a ticket to Paris at a reduced fare. Members who obtain tickets in this way must then re-book in Paris at the Orleans Station, and again present the card of membership so as to obtain the reduction of 50s. These arrangements will be in force on April 1st, and the tickets will be available until May 15th.

Assault on a Medical Man.

DR. FREDERICK JOHN HICKS, of Buckingham Gate, S.W., was the victim last week of a brutal assault at the hands of an irascible army officer who had taken offence at seeing his wife's photograph in Dr. Hicks's consulting-room. The magistrate, who declined to see anything objectionable in the photograph incident, characterised the assault as "most outrageous," and sentenced the offender to a month's imprisonment.

A Medical Student Thief.

HENRY THOMAS, age 22, a student at the London Hospital Medical School, was sentenced to nine months' imprisonment last week at the County of London Sessions for the theft of an overcoat belonging to a fellow student. No reason for the larceny was suggested, and the matter appears to be one in which an expert opinion on the mental condition of the accused might well have been taken.

Unqualified Dentist Fined.

AN unqualified dentist of Ashton-on-Mersey was fined £10 last week for describing himself as a "specialist on the teeth." His speciality was the painless extraction of teeth without an anæsthetic by the hypodermic injection of pure water.

Deaths under Chloroform.

A YOUNG lady at Harrogate died under chloroform administered for the purpose of an examination last week. Only two drachms of the drug, it is stated, had been administered. The usual verdict was returned. Another death under an anæsthetic was the subject of inquiry at Torbay, where an elderly woman died during an exploratory operation. In this case the A C E. mixture was used, and death proved to be due to the passage into the larynx of vomited matter. A verdict of death from suffocation was returned.

Pass Lists.

Trinity College, Dublin, Michaelmas, 1902.

FINAL Examination in Midwifery.—Seaton S. Pringle, Arthur A. Burrell, Anthony H. Corley, Thomas W. Crowley, Alexander H. Marks, Henry T. Brady; Walter G. M. Anderson and James E. Johnston; William Leggett and William P. Ringland; Walter R. H. Smith and Horace M. D. Townshend; Charles Ff. Rolleston; Thomas E. Ff. Manning and William I. de C. Wheeler; and Charles A. Stone.

(a) "Hygiene and Public Health." Parkes and Kenwood. Second Edition. Pages xii. and 763. London: H. K. Lewis. 1902

Notices to Correspondents, Short Letters, &c.

☛ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

J. D. E. (Buxton).—There is no ethical rule on the point, but our correspondent will understand that the best course to pursue is that which is governed by good taste.

Hollicops.—Saint Moritz, where the patient should remain until the end of next March, or the beginning of April.

Senex.—Our correspondent should consult a surgeon who devotes his attention to genito-urinary diseases. We cannot advise him further in the matter.

Colonial Surgeon.—Apply to the Dean of the West London Post-Graduate College, West London Hospital, Hammersmith, from whom full information can be obtained.

J. D. Most of the large Metropolitan hospitals have now Masonic Lodges connected with them. There are, however, two or three notable exceptions, for example, Guy's, University College, and King's The first two founded were the Rahere (St. Barts.) and the Cavendish (West London Hospital), each between six and seven years ago

Pes Anserinus.—The electric installation would cost about £40.

Meetings of the Societies, &c.

LONDON.

Wednesday, December 10th.

Pharmaceutical Society of Great Britain (17, Bloomsbury Square, W.C.).—8 p.m. Adjourned Discussion on Mr. J. C. Umney's paper on Drug Standards.

Dermatological Society of London (11, Chandos Street, Cavendish Square, W.)—5.15 p.m. Demonstration of Cases of Interest.

Hunterian Society (London Institution, Finsbury Circus, E.C.).—8.30 p.m. Clinical Evening.

Thursday, December 11th.

British Gynæcological Society (20, Hanover Square, W.).—8 p.m. Specimens will be shown. Paper:—Mr. S. Bishop: Procidentia Uteri. with Special Reference to an Operation upon the Sacro-uterine Ligaments.

Ophthalmological Society of the United Kingdom (11, Chandos Street, Cavendish Square, W.).—8 p.m. Clinical Evening. Cases will be shown by Mr Mayou, Dr. Edridge-Green, Mr. C. Blair, Dr. B. Potter, Dr. E. Maddox, Mr. S. Stephenson, Mr. N. C. Ridley. and Mr. E. T. Collins.

Medical Graduates' College and Polyclinic (22, Chenies Street. W.C.).—5.30 p.m. Mr. Mayo Robson: The Surgery of the Gall Bladder.

Friday, December 12th

Society for the Study of Disease in Children (11, Chandos Street, Cavendish Square. W.).—5 p.m. Special Meeting. Discussion on Tuberculous Peritonitis.

South-West London Medical Society (Bolingbroke Hospital, Wandsworth Common).—8 45 p.m Paper:—Dr. C O. Hawthorne: The Diagnostic Value of the Visual Field.

Clinical Society of London (20, Hanover Square, W.).—8.30 p.m. Papers:- Mr. S. Paget: The Subcutaneous Injection of Paraffin in Cases of Nasal Deformity. Dr. W. Carr and Mr. E. Roughton: Typhoid Fever, Perforation, Laparotomy, Death. Mr. A. A. Bowlby: A Second Case of Laparotomy for Perforation in Typhoid Fever, Recovery. Mr. H. J. Waring (introduced by Mr. A. A. Bowlby): Five Cases of Typhoid Perforation treated by Laparotomy.

Tuesday, December 16th.

Medical Graduates' College and Polyclinic (22, Chenies Street, W.C.).—5.30 p.m. Dr. Theodore Williams: The Diagnosis of Pulmonary Tuberculosis.

Appointments.

Boycott, A. E., M.A., M.B., B.Ch.Oxon. B.Sc. Oxon., Assistant House Physician to St. Thomas's Hospital.

Bradford, A. B., M.B., B.S.Durh., L.R.C.P.Lond., M.R.C.S., Assistant House Surgeon to St Thomas's Hospital.

Burghard. F. F., M.B.Lond., F.R.C.S.Eng., Teacher of Operative Surgery to King's College.

Carless, A., M.B.Lond., F.R.C.S.Eng., Professor of Surgery to King's College.

Cheyne, W. **Watson**, C.B., F.R.S., Professor of Clinical Surgery to King's College.

Child, F. J., M.A., M.B., B.C.Cantab., L.R.C.P.Lond., M.R.C.S., Senior Obstetric House Physician to St. Thomas's Hospital.

Coates, J., L.R.C.P.Lond., M.R.C.S., House Surgeon to St. Thomas's Hospital.

Hamilton, A. D., M.B., L.R.C.P.Lond., House Surgeon to St. Thomas's Hospital.

Hedley, J. P., M.A. M.B., B.C.Cantab., Assistant House Surgeon to St. Thomas's Hospital.

Henderson T. B., M.A., M.B., B.Ch.Oxon., Assistant House Surgeon to St. Thomas's Hospital.

Hildersheim, O., B.A., M.B., B.Ch Oxon., Clinical Assistant in the Electrical Department at St. Thomas's Hospital.

Hill, W., B.A.Cantab., L.R.C.P.Lond., M.R.C.S., House Surgeon to St. Thomas's Hospital.

Hudson, A. C., M.A., M.B., B.C.Cantab., House Surgeon to St. Thomas's Hospital.

Jones, B. S., L.R.C.P.Lond., M.R.C.S., Clinical Assistant in the Ear Department at St Thomas's Hospital.

Mavrogordato, A., L.R.C.P.Lond., M.R.C.S., House Physician to St. Thomas's Hospital.

Rob, J. W., B.A., M.B., B.C.Cantab., Assistant House Surgeon to St. Thomas's Hospital.

Scott, S. G., M.A., M.B., B.Ch.Oxon., Clinical Assistant in the Ear and Throat Departments at St. Thomas's Hospital.

Sears, C. N., L.R.C.P.Lond., M.R.C.S., Assistant House Physician to St. Thomas's Hospital.

Sedgwick, C. H., M.A., M.B., B.C.Cantab., House Physician to St. Thomas's Hospital.

Shipman, G. A. C., M.A., M.B., B.C.Cantab., L.R.C.P.Lond., M.R.C.S., Junior Obstetric House Physician to St. Thomas's Hospital.

Spurrier, H., B.A.Cantab., L.R.C.P.Lond., M.R.C.S., House Surgeon to St. Thomas's Hospital.

Wheen, C., B A.Oxon., L.R.C.P.Lond., M.R.C.S., Clinical Assistant in the Skin Department at St. Thomas's Hospital.

Vacancies.

Borough Asylum, Canterbury.—Assistant Medical Officer. Salary £120 per annum, with furnished apartments, board (except alcoholic beverages), and laundry. Applications immediately to the Medical Superintendent, Borough Asylum, Canterbury.

Brown Sanatory Institution.—The office of Professor-Superintendent will shortly become vacant. Salary £250 per annum. Applications to the Secretary. (See Advt.)

Children's Hospital Dublin.—Assistant Surgeon; House Surgeon. Salary 50 guineas per annum with apartments, fire, light, and attendance. Immediate application to H. C. Mooney, Hon. Sec. (See Advt.)

Essex and Colchester Hospital.—House Surgeon. Salary £100 per annum, with board, washing, and residence in the Hospital. Applications to C. L Becher Secretary.

Manchester Royal Infirmary.—Resident Medical Officer at the Convalescent Hospital, Cheadle. Salary £150 per annum, with board and residence. Applications to W. L. Saunder.

Rochdale Infirmary.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing. Applications to R. W. Shaw, Esq. Southfield, Rochdale.

Royal South Hants and Southampton Hospital.—House Physician. Salary £100 per annum with rooms, board, and washing found. Applications to T. A. Fisher Hall, Secretary.

South Devon and East Cornwall Hospital, Plymouth.—Secretary. Salary £300 per annum. Applications at the hospital to the "Chairman and Committee."

The General Hospital, Birmingham.—Resident Surgical Officer. Salary £100 per annum, with residence, board, and washing. Applications to the House Governor.

Birth.

Platt.—On Dec. 4th, at 18, Hall Road, Maida Vale, the wife of A. F. R. Platt, M.B., of a daughter.

Marriages.

Baxter—Richards.—On Dec. 4th, at Blandford, Dorset, Stephen Edward Baxter, M.R.C.S.Eng., L.R.C.P.Lond., of Wollaston, Northants. to Mary Emma, eldest surviving daughter of the late O. C. Richards, Esq., and Mrs. Richards, of Langton Villa, Blandford.

Carter—Wood. On Dec. 3rd, at Paisley, Frederick John Carter, M.R.C.S., L.R.C.P., son of the late Rev. Canon Carter of Linton, Kent. to Janet Lang, eldest daughter of John A. Wood, Esq., of Park Gate, Paisley. N.B.

Knyvett Gordon—Archer.—On Dec. 3, at St. John's, Walham Green, S.W., Alec Knyvett Gordon, M.B., B.C., B.A.Cantab., Medical Superintendent of Monsall Hospital, Manchester, to Gertrude Mildred, daughter of the late Major Lewis Archer.

Shepherd—McElney.—On Dec. 4th, at the First Presbyterian Church, Antrim, Thos. S. Shepherd, M.B., Ch.B., eldest son of Charles Dunbar Shepherd, Greystone, Arnside, to Elizabeth McElney, M.B., Ch.B., youngest daughter of the late William McElney, Randalstown, co. Antrim.

Deaths.

Berry.—On Dec. 5th, at 31, Sherriff Road, West Hampstead, Edward Unwin Berry, M.R.C.S., in his 92nd year.

Jackson.—On Dec. 6th, at 94, Broadhurst Gardens, Hampstead, N.W., Frederick, second son of J. T. Jackson, M.R.C.S., aged 52 years.

Kilgour.—On Dec. 4th at 2, Keynsham Bank, Cheltenham, John Stewart Kilgour, M.D., aged 87.

Langford.—On Dec. 3rd, at Sunnyside, Hornsey Lane, N., Charles P. Langford, M.R.C.S., &c., aged 67.

THE BROWN ANIMAL SANATORY INSTITUTION.

(Under the Government of the University of London).

The office of PROFESSOR-SUPERINTENDENT of the above Institution is about to become vacant, and applications for the appointment are invited. The salary is £250 per annum.

Applications should be addressed, not later than WEDNESDAY, DECEMBER 31st, to the Secretary of the Institution, 149 Wandsworth Road, S.W., from whom information respecting the duties of the office may be obtained.

December 9th, 1902.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

Original Communications.

THE CONTROL OF CONSUMPTION BY THE PUBLIC HEALTH AUTHORITY.(a)

By T. PERCY C. KIRKPATRICK, M.D.,
Assistant Physician, Dr. Steevens Hospital, Dublin.

IRELAND occupies the unique and unenviable position of still having an increasing mortality from tuberculous disease. Thus, in this country, in the year 1900, phthisis caused 10,076 deaths, out of a total of 87,606, or a rate of 225·6 per 100,000 of the estimated population, or more than one-ninth of the rate from all causes combined, you will see that it is time that we were up and doing if we do not wish to be left hopelessly behind other countries in the advance towards that satisfactory condition of public health which Preventive Medicine appears to promise. In other countries the efforts to prevent phthisis have been rewarded with a very marked degree of success. Thus, in the city of New York, the death-rate from phthisis has been reduced by over 30 per cent. since the adoption of preventive measures some ten years ago, and similar gratifying results have been obtained elsewhere. Let us consider then carefully the methods by which these results have been obtained, and by a study of the conditions existing in our own country see if we can learn any useful lessons for our future guidance.

As early as the year 1894 the campaign was opened in Manchester by the distribution of handbills to every house in the city, giving instructions in precautionary measures; but at that time there was no possibility of ascertaining whether the measures so advised were adopted or not. I think we may fairly conclude that, among the poorer classes at all events, very little attention was paid to such instructions. In order then to enable the public health authorities to exercise some supervision over such cases, and, where necessary, enforce the adoption of preventive measures, a very complete scheme was drawn up and adopted by the City Council in the year 1899, and this, with certain additions and modifications, has been in force ever since. The main lines of this scheme may be grouped under the following heads:—

1. Voluntary notification of consumptive cases.
2. Education of the public in general, and of the patient and his friends in particular, in the nature of the disease.
3. Treatment of the patient's surroundings.
4. Supervision.
5. Provision of isolation hospitals.
6. Protection of the food supply from contamination by the tubercle bacillus.

By far the most important part of this scheme, from an administrative point of view, is the adoption of notification, as without this the Executive has no means of knowing where the cases are, and so is unable to carry out effectively any preventive measures. In Manchester no attempt was made to bring phthisis under the provisions of the Infectious Disease Notification Act of 1890, but practitioners were asked to notify cases, and a scale of fees payable for such notification was drawn up. The names and addresses of the cases notified were registered and if it was thought advisible further steps were taken with a view to supervision and inspection. A very important adjunct to notification in the form of the free bacterial examination of sputum was undertaken for medical practitioners, so that in all cases the diagnosis could be confirmed. If such examination gave negative results the medical man was asked whether he still adhered to his diagnosis, and, if so, the case was considered one of phthisis from an administrative point of view. The education of the patient and his friends in the nature of the disease is personally undertaken by the assistant medical officer, who visits the house after the case has been registered. An effort is made to educate the public generally by the posting of notices pointing out the danger of promiscuous spitting in railway stations, tramcars, public-houses, common lodging-houses, workshops, &c.

As regards the treatment of the surroundings, the assistant medical officer reports any sanitary defects in houses visited, and they are dealt with by the ordinary methods of the Sanitary Department, while the special disinfection is carried out under the supervision of the sanitary inspectors. The ceilings are lime-washed, the walls rubbed down with dough, the floor, woodwork, and furniture are washed with ordinary soap and water. This process the inhabitants carry out themselves under supervision. If, however, the house is very dirty, or evidently infected, the Corporation disinfects the walls, floors, ceilings, and articles of furniture by washing with one per cent. of chlorinated lime, the paper usually being stripped from the walls in every case. The clothing, bedding, &c., are disinfected by steam.

Manchester has not yet been able to do much in the way of provision of hospital accommodation, either as sanatoria for the early cases, or isolation hospitals for the advanced cases, but in this respect there will probably be a marked advance in the future. Very elaborate precautions are adopted to prevent infection by either meat or milk; but in view of the pronouncement of Koch on the transmissibility of bovine tuberculosis, it is hardly to be expected that other places will adopt any new or expensive methods of prevention in this department while the question is still *sub judice*.

The adoption of precautionary measures in New York City is largely due to the energy of Dr. Herman Biggs, who has given such an admirable description of what has been done there. The first official action was taken in New York in the year 1889, when the Board of Health asked the consulting pathologists of the Department for a report on the causation and prevention of tuberculosis. This report was presented in the same year, and laid particular stress on the following points:—Tuberculosis is a preventable disease; it is not directly inherited, but transmitted from the sick to the healthy, chiefly by means of dried sputum suspended as dust in the air. From this report, presented twelve years ago, we learn as fully and completely as we can at the present day the nature of the problem that we have to deal with, and all subsequent work on the subject has simply confirmed and amplified these statements. On the receipt of this report the Board of Health consulted with many of the leading physicians of New York, and as a result decided that the medical profession and people were not prepared to accept active preventive measures founded on the belief that tuberculosis was an infectious disease. This being so, little was done except inspection of food and an endeavour to disseminate knowledge as to the nature of tuberculosis. So effectively, however, was this latter measure carried out that during the winter of 1893-94 the Board of Health, on the recommendation of Dr. Biggs, adopted certain resolutions giving effect to the following principles:—Notification, inspection and disinfection of infected dwellings. A request was made for the voluntary notification of cases of tuberculosis under the care of the physicians in the city. It was pointed out to the physicians that this information was solely for the use of the Department, and that in no case would visits be made by the inspectors unless the patient resided in a boarding house, tenement house, or hotel, except at the request of the attending physicians, and even in the case of such places if the physician requested that visits should not be made, and signified his willingness to afford the necessary instruction to the patients, no further steps would be taken by the Department. Compulsory notification was adopted in the case of public institutions, such as hospitals, prisons and asylums, &c. Visits of inspection with a view to affording instruction and to report on the necessity for further steps, were determined on in the case of tenement houses, boarding houses and hotels, except in those cases provided for above. In every case where the premises which had been occupied by a consumptive were vacated, either by death or removal, visits were made by the inspector, who directed the removal of infected articles such as bedding, carpets, &c., for free disinfection by the Department, while the owner was compelled to have the premises disinfected at his own expense. No person other than those residing there at the time were allowed to occupy such apartments till this order had been carried out. Bacteriological examination of the sputum was undertaken free of charge by the Department, provided that it was sent in bottles accompanied by a paper setting forth the name, age, sex, and address of the patient. Suitable bottles and blank forms to be filled in were supplied free to those who wished to make use of them.

(a) An Abstract of the Inaugural Address read at the Opening Meeting of the twenty-eighth Session of the Dublin University Biological Association, November 27th, 1902.

During the first year after the commencement of the work 4,166 cases of tuberculosis were notified, during the second year 5,824, during the third year 8,334, while in 1900 the cases numbered 11,997; the number of houses inspected has increased proportionally. As a result of this, Dr. Biggs is able to make the following statement:—

"There has been a reduction in the mortality from tuberculous diseases in New York City since 1866 of more than 35 per cent.; and I have no hesitation in saying that I believe with a complete and efficient scheme for dealing with pulmonary tuberculosis, including hospital accommodation and the proper enforcement of precautionary measures, the death-rate from the tuberculous diseases in New York City may be further reduced one-third within a period of five years. This would mean a saving of 3,000 lives annually."

I propose to devote the remainder of the time at my disposal in considering a plan of campaign which would be applicable to our conditions here.

It is no longer necessary to argue the question of the advisableness of municipal control of public health; it will, I think, be granted that under present conditions it is only by such authority that large questions of public health can be at all satisfactorily dealt with. Taking for granted then that the already constituted public health authorities are the proper bodies to deal with this question, let us consider what course of procedure we can recommend for their adoption.

It seems almost a truism to say that the first essential in the administration of any disease from a public health point of view is that the responsible authority should be in a position to know where the cases of that disease exist. The only way in which this knowledge can be obtained is by notification, and the only form of notification which has been found to work satisfactorily is compulsory notification. Although this is so, there is, perhaps, no point in the administration of preventive measures against phthisis which has been so hotly disputed, and about which there are so diverse opinions, as the adoption of compulsory notification. The advantages to be derived from notification are so obvious that it is unnecessary to dwell on them further than to say that without its aid it is difficult to see how any substantial progress can be made. Let us then examine the objections against it, and see if they are of such a nature as to compel us to abandon a means from which so much good is to be expected. Much confusion has arisen from the idea that if compulsory notification is adopted it is necessary to put in force in regard to phthisis all the provisions of the Public Health (Ireland) Act, 1878, and consequently render phthisical persons who expose themselves in public liable to the penalties which that Act entails. Such a state of affairs would undoubtedly be intolerable in the case of a chronic disease like phthisis; depriving, as it would, many who were well able to work, of their liberty, and involving the State in an enormous expense for their support.

There is no doubt that at first notification appears a hardship and a breach of that most sacred trust, professional secrecy; but we must remember that the principle has been accepted on the grounds of public utility, and in many cases in this country the provisions of the Act have been voluntarily adopted by the District Councils, though they are composed almost entirely of laymen. If the lay public wish to absolve medical men from this bond of secrecy, in definite cases and for definite ends, there does not appear any reason for objection on the part of the medical men themselves. Notification to the sanitary authority does not mean notification to the community at large, and, if carried out on the lines adopted in Manchester and New York, does not involve any hardship to the individual unless that individual, by his neglect of proper precautionary measures, makes himself a source of danger to the community. Surely in such cases the community has the right of protecting itself from such persons. There is one objection which I fear will carry more weight, in this country at all events, than all the others, and that is the expense involved. It is unreasonable to expect, and unfair to ask, medical men to work for nothing, and undoubtedly the notification fees in a city like Dublin would form a considerable item for some years to come. We must remember, however, that it is an item which will decrease rather than increase, and which promises the very best value for the money expended. No doubt the fact that one case would be notified again and again by different practitioners would add to the expense. This appears to be unavoidable; but the difficulty would, I believe, be greatly lessened if medical men were asked to try and find out, as far as possible, if the cases had been already notified. There is another difficulty, and one to my mind of much more importance than those already urged, and that is the impossibility in many of the early cases of making any sort of an accurate diagnosis without a bacteriological examination of the sputum. It would be out of the question to expect the busy and overworked dispensary medical officers to undertake such examination. Thus to make notification efficient some method of free examination of sputum must be devised. This, of course, would be quite simple if we were provided with a properly fitted bacteriological laboratory. The necessity for such an institution in the city has been urged again and again, but so far without result, apparently on account of the expense it would entail. Although such an institution would be of the utmost value, not only for the administrative control of phthisis, but for the sanitary administration in general, yet I believe that it would not be an absolute essential, at the outset at all events, in our campaign against phthisis. For the detection of tubercle bacilli in sputum no costly or elaborate appliances are necessary, and I believe it would be possible for the sanitary authority to carry it out even with the means at their disposal in the city at present. It is possible now in private cases to have the report of a skilled bacteriologist on tubercular sputum at the cost of three shillings. In the City of Manchester for the year 1901, specimens to the number of 517 were examined for the Public Health Authority, under the supervision of Professor Delépine, at Owens College. Would it not be possible for the Public Health Authority here to contract with pathologists in the various centres of the city to examine sputum, and report to them the results at a cost which would be quite insignificant compared with what would be necessary for the establishment and equipment of a laboratory? In Manchester during the same year 1,339 fresh cases of phthisis were notified, while 1,142 deaths were recorded; so that from these figures we may conclude that in Dublin the adoption of the scheme I have outlined would not be so very costly.

The immediate result would be to place the sanitary authorities in a position to deal with tuberculosis both effectively and cheaply. Let us see then what measures we can recommend to them for this purpose. The future extinction of tuberculosis can be hoped for only as the result of the combined efforts of the community, both lay and medical, and the only way that we can obtain such a combination is by the education of the public in the nature of the disease. One of the first duties then of the sanitary authority will be the diffusion of such knowledge. This will be much more simple and direct when given to the patients and their friends than when simply given to the public in general. Information about matters which personally concern us or our friends is much more likely to be fruitful than when to us it appears merely of general interest. The sanitary inspectors will be able to impart such information to patients of the poorer classes directly, and at the same time give instruction how the danger of infection of the healthy by the diseased may be avoided. For this purpose, as well as to see that the instructions given are carried out, regular and systematic inspection of the homes of the tuberculous should be carried out. The whole experience of sanitary supervision at the present day tends to show that such inspection will be welcomed rather than objected to, in spite of what *a priori* considerations would lead us to believe.

There is one other part of any scheme for the prevention of consumption to which I must allude—a part, too, which appears at the outset to be far the most formidable of all. I refer to the provision of isolation hospitals. In the first place, I should like to point out that the Public Health Authority has only to deal with, and provide for, the health of the community at large, and not with that of the individual. Consequently, it is only so far as the health of the individual affects that of the community that it comes within the jurisdiction of the Public Health Authority. Consumptive patients, then, come within the jurisdiction of this authority, because of the danger which exists of their spreading the disease, and because of their number, which causes such an important item in the increase in the death-rate. Were it not for the existence of the first of these two reasons the Public Health Department might completely neglect the consideration of phthisis. Take, for example, the case of cancer. The death-rate from this disease in Ireland during the year 1900 was 0·6 per 1,000, and caused 1,469 more deaths than small-pox, measles, scarlatina, and diphtheria taken together; yet since, so far as we know at present, a cancer patient is not in himself a source of danger to the community, the Public Health Authority takes no steps as regards his control. This is a point of great importance, since it absolves the Public Health Authority from direct responsibility for the provision of sanatoria for the cure of the disease. Of course, in so far as such sanatoria are a valuable means of prevention they come within the scope of this authority, but only so far. There are two separate and distinct classes to be dealt with in regard to hospital accommodation—those early cases in which permanent arrest or complete cure may be expected, and those cases which are so far advanced that no improvement beyond mere alleviation of symptoms can be hoped for. With the adoption of proper precautionary measures the first class need not be a source of danger to the public at all, and it is only in so far as they form the constant recruiting ground for the second class that it becomes our duty to try and cure them by the provision of sanatoria. Such patients, however, are isolated in sanatoria for their own good, and it is difficult to see how they could be compelled to enter such institutions against their will, provided they conducted themselves in such a way as not to be a source of danger to others. With the second class it is different, for since they are unable to work and support themselves they will in consequence be unable in the majority of cases to adopt the necessary precautionary measures, and so may fairly be compelled to submit to isolation. While then we look on sanatoria for the treatment and cure of phthisis as a most useful preventative measure, still they must not be considered as essential; and even without their aid we may hope for a very large measure of success in our efforts towards the stamping out of the disease. Let us see, however, if we cannot make more use of the means already at our disposal, for there is no doubt that in the near future, when the public become more alive to the necessities of the case, the provision of funds for the erection of sanatoria will be much more readily forthcoming. At the present time it is the rule in our Dublin hospitals to refuse as far as possible admission to phthisical patients, on the grounds that they are unsuitable for treatment in a general hospital. I say advisedly as far as possible, for cases are constantly presenting themselves with hæmorrhage or some other complication, which renders it impossible to refuse admission. In consequence of this you will constantly find phthisical patients in the general wards of our hospitals side by side with other patients who are, perhaps, in a condition which renders them peculiarly liable to the infection. That this state of affairs does exist I have satisfied myself by personal investigation, and under the present circumstances, do what we may, it must exist. Now, if each hospital were compelled to open at least one ward each, solely for the reception of phthisical patients it would be possible to isolate these cases, and the benefit from the point of view of the education of the patients would be enormous. I know that there are many objections to such a scheme, but none of them appear to me to be insuperable. First of all, we must remember that the hospitals are primarily for the benefit of the sick poor, and it seems unjust to exclude such a large and deserving class as the phthisical; while it is equally unjust to submit those who are not so suffering to any unnecessary risk. Thus, quite apart from any anti-tuberculous campaign, there is a distinct need for some such arrangement. Then we are told that the air of a general hospital is most unsuitable for the treatment of such cases, but we must remember that very many cases are greatly benefited, when suffering from some complication such as hæmorrhage or an acute attack of bronchitis, &c., by a few weeks' residence in hospital. In such cases it may make all the difference to the possibility of their future cure. Again, in cases which are rapidly approaching their end such wards would be most suitable, as it is far more preferable that they should disseminate their infection in a ward reserved exclusively for persons with the same disease than that they should do so in their own homes. I cannot believe that these wards, if properly cleaned and periodically disinfected, would be a source of danger in themselves. The chief objection is on the score of expense—the hospitals say that they cannot afford to open special wards, but the expense would be trivial compared with that which would be necessary for the erection and establishment of special sanatoria. If the Corporation and Trustees of the Hospital Sunday Fund would make some extra special grant to hospitals which provided such wards this objection would probably vanish at once. I do not wish to be understood as claiming that such a scheme would do away with the need for sanatoria altogether, but it would satisfy the pressing need for them from the point of view of the Public Health Authority, and so greatly lessen the initial expense of our campaign. It seems hardly possible to apply the insurance system towards the maintenance of sanatoria in this country, as has been done with such success in Germany. Free medical attendance is so easily obtained by everyone of the working class that any attempt to establish such a system of insurance, if the premiums had to be deducted from the weekly wages, would probably meet with great opposition. Most of our large trading and manufacturing companies do provide medical attendance, not only for their employés but also for their wives and families. It is just in this class that consumption is most rife—that is, among those who have to spend their lives in factories and workrooms, where the most favourable conditions for infection are to be found. Would it not be possible for some of the great trading companies to join together for the purpose of founding and maintaining sanatoria for the treatment of consumptives among their employés and their families? I feel sure that the funds so used would not be grudged by the shareholders, and the good which would result from such a scheme would be incalculable.

A PRACTICAL COLOUR-TEST.

By KENNETH SCOTT, M.B., F.R.C.S.,
Consulting Ophthalmic Surgeon to St. Mary's Children's Hospital, E.

THIS test is essentially for the practical purpose of proving the efficiency, or otherwise, regarding the correct appreciation of colour, of those wishing to be employed on railways, in navigation, or any other occupation, where directions are conveyed at times by signals formed of coloured lights. It is the power of instantly and correctly recognising the coloured lights so employed, and not the relative comparisons of tints or shades of colour, which is required from such individuals. The test now described does not replace or supersede the more minutely detailed examination for colour-perception, either qualitative or quantitative, which may be additionally investigated whenever necessary.

As only four colours are ordinarily used when signalling with lights, the colours in this test are similarly limited; and when the examiner is satisfied that these can be quickly and correctly recognised in a practical manner, there can be no hesitation in stating that the individual under question is perfectly qualified, in this special particular, for employment in any of the avocations just mentioned.

The colours referred to are a bright white or clear yellow light, also red, green, and violet-coloured lights. Artificial illumination is used so as to more closely simulate the actual working conditions, and the various coloured glasses are interposed in front of it, a piece of frosted glass also being introduced among the coloured ones for the purpose of confusion.

A disc in which these glasses are mounted, revolves, in front of an aperture, on the ordinary shield screening the opthalmoscopic lamp, or on an asbestos or other chimney specially used for the purpose; there are five round apertures, of about 10-15 mm. diameter each, at regular intervals near the margin of the disc; one of these is unoccupied, and the other four are each filled by a piece of red, green, violet (or purple) and plain frosted glass. The degree of illumination coming through the aperture, can be modified by the use of an iris-diaphragm, or by the intervention of another separate disc, revolving on the same axis as the previous one, and with a series of holes pierced in it, ranging from 1-6 mm. or larger, in diameter. Another piece of frosted glass mounted on a separate small arm, and placed so as to work on the same axis as these two discs, can be combined with any of the other glasses in order to still further modify or diminish the intensity of the rays of light which pass through. There is no need to change the distance at which the test-lamp is placed during the examination, to obtain the alteration which would occur in the light if it were seen under actual working conditions at a far distance, as the colour-test offers variations which are sufficient for this purpose.

When the foregoing means are not available, a simple and almost equally practical, and similarly accurate, method for arriving at a proper conclusion as to the power of colour discrimination is to employ a series of rounded pieces of paper, 35-40 mm. in diameter, of the same colours as the lights—pale yellow, red, green, and violet; these are placed on a dark background which has a dull surface. These are mounted on a board, at each end of which there are eyelets, so that it can be suspended from either end, or, by using both eyelets, it may be placed with either of its sides uppermost. This yields endless variation and change in the relative positions to each other of the colours; consequently their sequence cannot become committed to memory or learned by rote through frequent repetition, thus maintaining a sufficient and proper standard of unfamiliarity in the test. This possibility of completely and instantly transforming the appearance of the chart, also allows of the colours being indicated by name in the first instance, if deemed necessary, to the individual under examination, as it does not at all detract from its intrinsic value; this too, may be done when using the colours-test lamp. It is by no means an unknown fact that candidates have failed to pass in an examination, simply and entirely from insufficient knowledge, or even complete ignorance, of the *names* of the different colours, although at the same time being fully competent to otherwise distinguish, and unerringly recognise them. (*a*)

LATE DISEASE OF THE BRAIN AFTER INJURY.

By HR. STADELMANN,
Of the University of Berlin.

CASES of this kind were described long since by Bollinger. The diagnosis was most difficult when the so-called late bleedings came on weeks or months after the injury. I would rather call such cases late apoplexies in distinction to traumatic secondary hæmorrhage. A large series of such cases had been collected by Matthias and Bruns. An old man had received a blow on the head. There was no loss of consciousness, only headache; the man was away from his work a few days, and then looked up again. Later on he again became unwell, with headache, nausea, vomiting and loss of consciousness, and died. The autopsy revealed softening and hæmorrhage into the brain. Here the question came in as to the connection between the injury and the apoplexy, as softening in old people was not rare, and at first presented few symptoms. Those cases were more doubtful when a longer period such as a year intervened, and when the individual, in addition to the cerebral hæmorrhage, had nephritis, arterio-sclerosis, or other diseases. The encephalitis would be looked upon by many as a result of the injury; others would attribute it to the later arterio-sclerosis. Friedmann had reported a series of such cases. Here serious criticism was wanting. Thus, for example, in a case where cerebral changes were attributed to an injury suffered twenty-three years before. That arterio-sclerosis could come on in such cases by an unsuitable mode of life, want of exercise, improper feeding, &c., was possible, but no direct connection between the injury and the cerebral disease could be proved.

(*a*) These apparatus are made by the Anglo-American Optical Company, 47, Hatton Garden, London, E.C.

In order to bring the cerebral changes into connection with the disease, the following conditions must be fulfilled :—1. The patient must have been healthy and sound before the receipt of the injury, and must not be of great age. 2. The injury must have been considerable. 3. The symptoms must have developed before our eyes. According to some authors, the diseased vessels must be opposite to the injury. The speaker recognised the occurrence of late disease after injury to the skull. After injury, disturbance of circulation followed, and from this softening and late hæmorrhage. He related the following case that was sent to him for an opinion. A man, æt. 47, was at work in January, 1900, when a stone fell upon his head. He had previously been perfectly healthy ; there had been no syphilis. Two and a half years afterwards the patient was examined. He was very stupid, complained of giddiness and headache, otherwise he was in good condition and the internal organs were sound. There was great loss of mental power, the man knew nothing definite about his previous injury, could not say what month or week it was, and could not do the simplest arithmetical problems. According to the report, the patient had lain unconscious after the accident for about five minutes, was taken home, and had scarcely thought of the accident afterwards. He was attended for several weeks on account of the wound on the scalp, and had kept his bed a few days. After four to five weeks he became much depressed, and had attempted suicide twice. Since then his condition had got gradually worse, depression alternated with maniacal attacks. He had been treated in six different institutions without result. He had formerly been addicted to alcohol, but he could no longer bear it. There was a cicatrix tender on pressure at the site of the injury between the frontal and temporal lobes, which was not fixed to the underlying bone. In this case serious cerebral changes took place in consequence of the injury, although the first symptoms did not present themselves until four weeks after receipt of the injury.

A second case was that of a man, æt. 29, who was brought unconscious into his wards. On the following morning he had partly regained his speech, but could not pronounce properly. From his wife it was gathered that four weeks previously he had received a blow on the head, had fallen unconscious, but had quickly recovered himself and been bright and well since. In spite of a wounded head he had gone to his work, and had been in good spirits. Suddenly in the night he had been attacked with convulsions, and became unconscious and taken to hospital. He had not suffered from syphilis, and had not been a drinker. At that time there was no paralysis, his mind was not clear, and he mostly slept; the internal organs were healthy. On examination, a cicatrix fixed to the bone was found near the motor centre. Epileptic attacks now came on, always starting from the left arm. These, followed by unconsciousness, became worse, so that the only hope lay in an operation. Hæmorrhage from the dura in an abscess was thought possible, but at the operation no hæmorrhage was found and no abscess. The patient got steadily weaker, pneumonia set in, and he died. At the autopsy nothing abnormal was found in the skull, but in the region of the motor centre on the right was a softening and deep hæmorrhage that had made a cavity for itself. He explained the condition in this way : the blow was from behind, the head being bent; softening and hæmorrhage had been caused by contrecoup. Such cases were of great forensic importance, and the case had occupied the courts, the assailant being sentenced to a long imprisonment.

A third case was related, in which a man was brought unconscious into hospital on November 17th, 1901. Seven weeks before he had fallen and struck the back of his head. After a short loss of consciousness he went home and in a few days returned to work, but always complained of headache. Then suddenly, seven weeks after the injury, he had a rigor with following fever, vomiting, and hallucinations, and was taken to hospital. The internal organs healthy. Lumbar puncture gives purulent fluid containing numerous staphylococci and pneumococci. Death took place in a few days. The post-mortem showed purulent cerebro-spinal meningitis. There was a fissure in the skull only partly healed. It was a rare thing for a fracture to heal, and for meningitis to come on seven weeks afterwards. Such observation showed us that cases with serious head injuries should be kept a long time under notice. The speaker always kept them in bed for at least four weeks, and did not dismiss them for at least six.

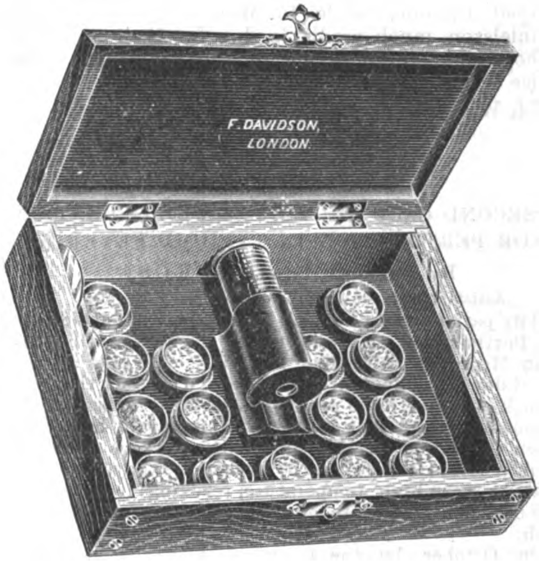
AN IMPROVED MODEL EYE.

By PERCY DUNN, F.R.C.S.,

Ophthalmic Surgeon to the West London Hospital; Lecturer on Ophthalmology at the West London Post-Graduate College.

The next best thing to practising retinoscopy and the use of the ophthalmoscope with the human eye is to employ an appliance which almost answers the same purpose.

Believing, however, that a model eye completely fulfilling these requirements has, so far, not been available for practitioners and students, I proceeded, some time ago, to devote attention to the subject, and I now venture to think that the result described below will be helpful in supplying the need indicated.



The model itself is an improvement upon a design which has for some years been known in America. It consists of two brass (blackened) cylinders, one of which is fixed on a stand, the other being movable, sliding backwards and forwards inside the former. On the movable cylinder is a printed graduated scale by which a maximum of myopia of 6 D. and of hypermetropia of 6 D. can be measured. At one end of the fixed cylinder is a lens of 2 ins. focus, thus enabling the observer, by altering the position of the movable cylinder, to produce various degrees of ametropia. The beginner, for example, might make the model eye myopic to 4 D., and proceed with the lenses taken from an ordinary trial case to estimate the defect; having arrived at the correction he can then ascertain by looking at the graduated scale whether his result corresponds therewith. Furthermore, different lenses are provided with the model, by which various degrees of astigmatism can be created by merely inserting one or other of the lenses in front of the lens in the fixed cylinder. In addition a diaphragm is supplied, to be placed in the slot in front of the 2 in. lens, for the purpose of representing the pupil in an undilated state.

For the study of changes in the fundus, seventeen metal discs are provided, so made as to cover the outer end of the movable cylinder, each containing an ophthalmoscopic drawing. On the reverse of these discs a number is placed which corresponds with a number on a printed list fixed inside the lid of the box, the idea being that the student should first examine the drawing with the ophthalmoscope in the ordinary way, and make a diagnosis of the condition of the fundus depicted before referring to the list. The following is the list of drawings in question :—

(1) Optic neuritis. (2) Posterior staphyloma. (3) Coloboma of the choroid. (4) Normal eye. (5) Retinitis pigmentosa. (6) Opaque nerve-fibres. (7) Syphilitic neuro-retinitis. (8) Detachment of the retina. (9) Sarcoma of the choroid. (10) Advanced chronic glaucoma. (11) Sub-hyaloid hæmorrhage. (12) Albuminuritic retinitis. (13) Post neuritic atrophy. (14) Disseminated choroiditis. (15) Embolism of the central artery of the retina. (16) Rupture of the choroid. (17) Primary atrophy of the optic nerve.

The model is manufactured and supplied by Mr. F. Davidson, optician, 140, Great Portland Street, W., to whom I am much indebted for the skill and care with which my ideas have been carried out. The ophthalmoscopic drawings were all executed by Mrs. Davidson, whose artistic talents are well displayed therein; while to Messrs. Bale, Son and Danielsson much credit is due for their excellent lithographic reproduction of the drawings. The price of the model is very moderate.

54, Wimpole Street, W.

Clinical Records.

A SECOND CASE OF SUCCESSFUL OPERATION FOR PERFORATION IN TYPHOID FEVER. (a)

By Anthony Bowlby, F.R.C.S.,
Assistant Surgeon to St. Bartholomew's Hospital.

The patient was a boy, æt. 10, who was admitted into St. Bartholomew's Hospital under the care of Dr. Norman Moore on September 1st, 1900. He was in his third day of typhoid fever, and beyond the fact that the attack was severe and prolonged, it called for no special comment, except that after the temperature had come down to normal on the thirteenth day, he suffered from a severe relapse on the twenty-first day, and had again a very high temperature, reaching to 105·4° on one occasion. The date of the relapse was September 19th.

On October 1st the temperature was still above normal (101°), and tympanites, which had been present throughout, was still well marked. There was also some crepitation at the bases of the lungs.

On October 2nd, after a slight shivering fit he became blanched and cold, his temperature sinking to 97·6°; but there was no subsequent evidence of hæmorrhage and no pain.

On the 3rd he seemed better, but the temperature was still 101°. The abdomen was less distended, and the bowels acted without enemata.

On the 4th his temperature was normal, but the abdomen was again distended. Pulse 96. A little before three in the afternoon he complained of some difficulty in micturition, and while passing his water was seized with severe pain in the abdomen. His temperature half an hour earlier had been 102·6°, but after his attack of pain he sweated profusely and the temperature dropped to 98°. For about half an hour the boy was screaming with pain and exceedingly restless. Then he became quieter and collapsed with sunken eyes, a cold sweat and shivering. The pulse had gone up meantime to 140.

I saw him at 4.30 p.m. with Dr. Norman Moore, and found his general condition as above described. The abdominal wall was hard and fixed during respiration, and I quite agreed with Dr. Moore that perforation had almost certainly taken place. and quite concurred with his proposal that an operation should be conducted at once.

At 5 p.m., therefore, two hours after the symptoms of perforation, the abdomen was opened in the middle line and free pus was at once found in the peritoneum. A considerable quantity of almost clear fluid welled up, but there was no large collection of fæcal matter. The intestine was so much distended that several coils of it had to be allowed to extrude, and were kept wrapped in hot towels. Many patches of inflamed peritoneum indicated the affected Peyer's glands. I then sought for the cæcum, and after finding it I rapidly passed the small intestine through my hands till I found a perforation situated less than two feet from the ileo-cæcal valve. The bowel was not adherent or otherwise altered, nor could any induration be felt in its walls, but the peritoneum corresponding to the shape of a Peyer's patch was very red and injected. The opening in the intestine was quite small, being not much larger than a pin's head.

I wiped the bowel clean, and then closed the opening by five Lembert sutures of fine silk. The greater part of the incision was now closed, and a glass drainage-tube was placed in its lower end. Owing to there being no complications the operation was completed in about twenty minutes, and at the end of it the patient's general condition was none the worse for the handling and exposure of the bowel. The peritoneum was not touched, but the intestines were carefully wiped clean, and all fluid was completely mopped up from the pelvis and elsewhere with sponges

For several days the boy remained very ill, and the morning after the operation the pulse was still 150, the temperature being 100·4°. There had been no sickness, and flatus was passed. He was fed by nutrient enemata, and only a little water or ice was given by the mouth. The abdomen remained distended. After this time there was steady and rapid improvement except for some sickness on October 7th, and a troublesome cough, so that by October 10th, six days after operation, the boy seemed to be convalescent.

On that day, however, he had a slight epileptiform attack, and in the evening a more severe and prolonged series of fits, necessitating the administration of chloroform. This threw him back and weakened him, but he again rallied, and in spite of a return of severe convulsions on October 20th, he ultimately recovered. The tympanitic distension of the abdomen which had been so marked throughout continued until the end of his illness.

I saw the boy some months later and found him to be in excellent health.

I have already recorded, about five years ago, a similar case of perforation of a typhoid ulcer in Vol. LXXX. of the Royal Medical and Chirurgical Society Proceedings (in conjunction with Sir Lauder Brunton), and in that case also, which had a similar satisfactory ending, the patient was operated upon late in typhoid fever, for he was in the sixth week of the illness, and was at the time suffering from a relapse. In that case there was much induration of the perforated Peyer's patch, and some consequent difficulty in suturing the ulcer, but in all other respects the cases had much in common, except that the boy whose case I now record was much more ill and disturbed at the time of the operation than was the first patient.

These two cases represent the only patients I have operated upon, and there can be no doubt that they represent two lives saved. But, on the other hand, I do not regard them as at all typical cases of typhoid perforation, but rather as typical of a special class in which perforation occurs after the fever is practically over, and in which the general condition of the patient is otherwise relatively good.

(a) Notes of case read before the Clinical Society of London, December 12th, 1902.

In such patients as these the symptoms of perforation are generally well marked, and the diagnosis is readily arrived at. But in very many other cases the reverse is true; for it not infrequently happens that perforation occurs when the fever is yet high, in patients who are nearly or quite unconscious, in whom there is no perception or expression of pain, and who may have distended tympanitic abdomens before perforation occurs. Many such patients are already at death's door, and in not a few of them, in addition to the perforation, there are, moreover, other areas whose very intestine is so rotten that its giving way is only a question of time.

It is not to be supposed that even if an ulcerated bowel is sutured many such patients soon recover, and in some of them at least the operation of suture may be practically impossible.

I saw at least one such case in South Africa, with Dr. Porth, in which the patient was quite unconscious and manifestly dying. Dr. Porth suspected that there might be a perforation, but as the symptoms were not clear no operation was undertaken, and the same day the man died. A post-mortem examination showed that the intestine was so matted and adherent to the omentum and mesentery that even after death it could with difficulty be unravelled, and though there was a perforation I do not think that it would have been discovered by operation, even if the patient's condition had permitted one to be performed.

As surgeons we are, of course, entirely dependent on physicians for the opportunity of operating on cases of perforation in typhoid fever, and it is evident that it is for us to convince them that operation may save life. The case I have recorded is one in which the saving of life was primarily due to Dr. Norman Moore, and in recording it I do not wish to suggest that all cases are likely to be so successful. On the other hand, I do think that in the present position of intestinal surgery there is good reason to advocate that the chance given by operation should not be withheld in any case of perforation, and I would suggest that in all such cases where perforation is suspected a surgeon should be called in as promptly as possible.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Meeting held Friday, December 12th, 1902.

Mr. A. Barker, F.R.C.S., Vice-President, in the Chair.

Mr. **Stephen Paget** read a paper on

TWENTY-FIVE CASES OF SUNKEN NOSE TREATED BY THE SUBCUTANEOUS INJECTION OF PARAFFIN (FOUR PATIENTS SHOWN AFTER OPERATION.)

Of the whole number of cases, eight were women and seventeen were men; the youngest was 19, and the eldest was 52. In many cases the nose had been deformed for very many years, and, in one case, for half a century. In his earlier cases Mr. Paget had used Eckstein's paraffin, but he was quite certain that it had obvious disadvantages and no advantage of any sort or kind over a paraffin melting 25° or 30° lower. The right melting point for nose cases, was between 108° and 115°, and he was using now a paraffin melting at 111°. Of many syringes that he had tried, the best was Eckstein's syringe; it kept its heat well, it could be easily worked with one hand, and it had a screw-nut on the piston, which prevented any possibility of a sudden running-in of paraffin; but it ought to have a short and strong steel needle. He thought it wrong to attempt to raise the skin, before injection, with a tenotomy-knife; but, if there had been exfoliation of bone, so that there was a depressed and adherent cicatrix, it might be advisable to free the skin at this one point. He drew attention to various details of procedure, and emphasised the fact that every paraffin, when it sets, shrinks; and the paraffin that sets the hardest shrinks the most. This inevitable shrinkage might be so slight as to be hardly visible; but, in many cases, it involved the addition, about a week later, of a few more drops of paraffin; this was done under cocaine. He had no disaster or calamity of any kind to confess, and he believed that in these nose cases there was practically not the very least risk of embolism. The results, taken all together, were very good: and it was easy, in nine cases out of ten, to achieve a vast improvement, and, in many cases, to alter the whole look of the face. It was not possible to make perfect Greek noses; in some, the face was short and small and square, and there was no room for a Greek nose; in some the nose was so shrunken by syphilis, and the upper lip so elongated, that complete success was impossible; in some, the end of the nose was coarse and clumsy, with thickened skin, and this could not be altered. But, short of perfection, an immense amount of good could be done. The skin between the eyes could be so raised and moulded that a fairly good-looking upper part of the nose could be made, improving the whole character of the face and the look of the eyes; the nose could be slightly lengthened, both in its real length and in its apparent length; and the tip of the nose could be depressed, so that the nostrils looked more directly downward. No two cases were alike; he had that day done two cases, which looked almost exactly alike, but in one of them he had failed to do much good; in the other it was perfectly easy in a few minutes to make a very fair good-looking nose. A nose that had been absolutely flat and ape-like for many years might be made at least unnoticeable, so that it should not distress and hinder a man all through life.

Dr. **Scanes Spicer** said he had seen some of the author's cases, and he congratulated him on the results he had obtained. He related two cases of his own in which he had employed this procedure and showed models. He had used paraffin with a melting point of 114° F., and in one case the eyelids subsequently became œdematous and presented hard nodules, and finally the left palpebral fissure became closed. With the assistance of Mr. Juler the masses were dissected out, and were found to consist of scales of paraffin deposited in the fibrous tissue. He remarked that the use of paraffin melting at a temperature of 136°F. would probably be found more satisfactory.

Mr. **Stephen Paget**, in reply, remarked that the melting point was a matter of importance, because if it were too high actual burning of the tissues would be caused.

Dr. **Walter Carr** and Mr. **Edmund Roughton** on a case of

TYPHOID FEVER; PERFORATION DURING A RELAPSE; LAPAROTOMY; DEATH ON THE THIRD DAY FROM A SECOND PERFORATION.

A girl, æt. 18, was admitted to the Royal Free Hospital on October 7th, 1902, on the ninth or tenth day of an attack of typhoid fever. The disease was of a severe type, both the local and the constitutional symptoms being well marked. At the end of the third week there was a small intestinal hæmorrhage. An intercurrent relapse commenced at the end of the fourth week, so that the temperature was never normal for the whole twenty-four hours, and at the end of the fifth week fresh spots appeared. On November 6th, about the fortieth day of the disease, well-marked signs of perforation developed, and an hour later the abdomen was opened an inch to the right of the middle line. A perforation, about one-sixteenth of an inch in diameter, was at once found and closed by a double row of Lembert's sutures. As there was very little fæcal extravasation, the soiled intestine was merely sponged with plain gauze, no washing out nor irrigation used, and no drainage employed. The operation only occupied nineteen minutes. Patient rallied well and progressed favourably for about sixty hours, then symptoms of perforation again developed and death followed three hours later. At the autopsy the first perforation was found to be firmly closed and there was no peritonitis round it, but a second and recent perforation was discovered a few inches lower down and was evidently the cause of death. The conditions which favoured the comparative success of the operation for the first perforation were discussed, viz., its early performance, the small size of the perforation, and the ease with which it was found and closed, so that the operation was a very short one. The chances of a second perforation were considered, the risk of this being probably considerable when perforation occurs during the acute stage of the fever. It was pointed out that whilst seven cases in all had been recorded in the United Kingdom of recovery after operation for perforated typhoid ulcer, all the patients were either convalescent or else suffering from a very mild form of the disease, and that so far not a single successful operation had been recorded in cases of a severe type, or whilst the patient was still seriously ill, although it was under such circumstances that the majority of perforations in typhoid fever probably occurred.

FIVE CASES OF PERFORATION OF THE INTESTINE IN ENTERIC FEVER TREATED BY OPERATION.

Mr. H. J. Waring gave a clinical account of five patients upon whom he had operated during the past four years for intestinal perforation during the course of enteric fever. The most noteworthy points in connection with this series of cases were discussed as follows :—

(a) *The seat and character of the perforation.*—In four of the cases the perforation was situated in the lower twelve inches of the ileum (4, 5, 12, and 14 inches respectively), and in the fifth case in the lower part of the sigmoid flexure sixteen inches above the anal margin. Two of the cases had a double perforation, and in each of these the perforations were close together. This observation, he stated, was in agreement with other statements which have been made on the subject. On this account he advised that when an operation is performed the lower one or two feet of the ileum should be first examined, next the region of the cæcum, vermiform appendix and the ascending colon, and then the sigmoid flexure. As regards the method of suturing the perforation he used in all cases fine silk, each suture being introduced by Lembert's method. Catgut was not considered to be suitable, on account of its thickness and the short time that elapsed before it was absorbed. Careful suturing was advocated on account of the possibility of perforating another ulcer in the region of the sutures. This accident had occurred in one of the recorded cases. Excision of the margins of the perforated ulcer was not advised on account of the probability of invading other ulcers and also on account of the extra time required for the operation and the increased shock to the patient. (b) *The most suitable period for operation.*—The time of operation in the recorded cases was 6, 8, 9½, 30, and 38 hours after the occurrence of the perforation, as judged from the clinical histories of the cases. The patients who recovered were those operated upon at the eighth and ninth hour, the others being fatal. He strongly advocated the performance of an operation as soon as it could be carried out after the perforation had been diagnosed, and considered that the earlier the operation is performed the greater are the chances of the patient's recovery. When time is lost in making a diagnosis, or in obtaining the services of a surgeon, the greater are the probabilities of the establishment of acute peritonitis. Four of the recorded cases undoubtedly had acute peritonitis in the recto-vesical pouch and the adjacent portion of the peritoneum at the time of operation; three of these died, one recovered. In the fifth case the coil of intestine which had perforated was adherent to a portion of the great omentum and the deep aspect of the anterior abdominal wall. This patient recovered. (c) *The period of the disease at which the perforation takes place.*—He stated that published accounts of cases seem to show that the later the stage of the disease, the greater the chances of recovery. He considered that success depended upon the early performance of the operation, the general condition of the patient at the time of perforation and the effects the disease had produced upon his vitality. In the recorded cases perforation occurred on the fourteenth and forty-second days in the successful ones, and the twenty-first and twenty-third in those which were fatal. As regards the fatal results in two cases he considered that the period of operation (thirtieth and thirty-eighth hour) was the main factor, and in the remaining one the severe form of the primary disease.

Mr. Anthony Bowlby related "A Second Case of Successful Operation for Perforation in Typhoid Fever," which will be found on page 652.

Dr. Norman Moore pointed out that the great difficulty in these cases was that of deciding whether perforation had actually occurred. He related the case of a boy in hospital, supposed to be in the fourth week of an attack of typhoid fever, who suddenly complained of great pain on the left side of the abdomen. As this did not improve in the course of an hour he was operated upon, *i.e.*, within two hours of the onset of the acute symptoms. In another case the patient had a colic-like attack of pain with symptoms of collapse at eleven o'clock and he was operated upon at two and recovered. He insisted upon the fact that to make the diagnosis in these cases it was necessary to observe the patient closely for some time, taking care not to be led away by a first impression.

Dr. F. de Havilland Hall related the case of a lad, æt. 16, with a severe primary attack of typhoid fever, who was seized with pain and vomiting, which he attributed to an attack of influenza in the gastric form, other patients in the ward subsequently developing similar symptoms. In this case the abdomen was throughout very tympanitic, which masked the liver dulness, so he decided not to operate. The patient died, and on post-mortem it was found that one ulcer had perforated but there were three or four others on the point of perforating. He said he brought forward this case to illustrate one of the difficulties of diagnosis.

Dr. Goodall concurred in the view that the great difficulty was to make up one's mind whether perforation had actually taken place, and he raised the question whether they would be justified in having recourse to laparotomy when there was only a suspicion of perforation, a point which had been discussed by Dr. Osler on various occasions. He advocated incision in the middle line, because the perforation might not be in the usual spot, and, moreover, other complications, such as perforation of the gall-bladder, &c., might be met with. Their experience at the Metropolitan Asylums Board hospitals had not been favourable. He asked what their opinion should be as to giving opium in these cases. He mentioned that in sixteen cases which had been published, with only one recovery, this was one in which the peritonitis was localised, while in the others it was general. He pointed out that perforation seldom occurred before the third week, and in both of Mr. Bowlby's cases the patient was practically convalescent.

Dr. Owen Fowler said that post-mortem experience showed that when perforation occurred in the active acute stage only one ulcer might have perforated, but several others were on the point of giving way. Probably operations undertaken in the early stages of the disease tended to bring the operation into discredit. Later, if an ulcer ruptured, laparotomy might save life. These cases were almost of necessity hospital cases, because in private practice there was so much delay that little chance was afforded of saving the patient.

Sir Richard Douglas Powell, Bart., pointed out that in many of these cases there was more than one perforation. He agreed that perforation occurred most frequently after the third week, at which time all the ulcers likely to perforate were pretty much in the same stage. If in a case with a high temperature there was a sudden fall, with pain and distension of the abdomen, loss of liver dulness and collapse, running pulse, sweating, cold extremities, &c., there could be little doubt as to the diagnosis, although no one sign would perhaps be sufficient. He pointed out that the operation would often relieve the patient by abating the extreme abdominal distension which was causing reflex paralysis of the heart. He referred to a case of Dr. Sayer's, of Ampthill Square, N.W.; that of a man who had been ailing for a month although he continued to get about. One day he was suddenly seized with a high temperature, and on the third day after that he had severe pain in the lower abdomen with symptoms of collapse, not attended by any abdominal distension. When he saw the man some hours later he was markedly collapsed and no improvement had taken place on the following morning, and soon after he died. Post mortem, they found a large perforation in the ileum and two other minute perforations elsewhere, so that an operation in this case would have been useless.

Dr. A. E. **Russell** said that at St. Thomas's they had had three cases of successful laparotomy for perforation in typhoid fever. The first was in a patient suffering from a second relapse, the second a man, æt. 21, in a first relapse. In this case so much relief was afforded by drawing off his water that a positive diagnosis was not arrived at until the following morning, when Mr. Battle operated over the seat of pain and came at once upon the perforation. He pointed out that absence of liver dulness in a contracted abdomen was a significant sign of perforation.

Dr. **Sydney Phillips** referred to several cases in which, in the course of post-mortem examinations, healing perforations had been seen. In none of these had the lesion been diagnosed during life. One difficulty in the diagnosis was that perforation sometimes gave rise practically to no symptoms at all, or but of the slightest, and, on the other hand, symptoms suggesting perforation might be brought about by quite other causes, and he referred to a case related before the Royal Medical and Chirurgical Society, in which all the symptoms of perforation were present, yet on operation no perforation was discovered, the patient recovering nevertheless. He did not think they would be justified in operating on mere suspicion, although much would depend on who suspected it. His own experience did not bear out the view that perforation usually occurred so late in the disease, and in these cases it would be interesting to know what had been the diet and the treatment. He pointed out that perforation was often preceded by pain in the abdomen, and assistance might be derived from the bell sound over the whole of the abdomen as showing the presence of free air. In the only two cases in which he had advised operation they had not been successful.

Mr. F. C. **Wallis** said a friend had told him that at Freiburg they were in the habit, in suspected cases of perforation, of flushing out the peritoneum with normal saline solution.

Dr. H. J. **Curtis** advocated laparotomy under local anæsthesia and drainage in suspected cases of perforation.

Mr. **Bowlby**, in reply, thought that where there was reasonable probability of perforation they ought to operate. The majority of those in whom perforation occurred were in a condition to support the operation, which, after all, was by no means a severe one.

Mr. **Waring**, in reply, said he had seen a person supposed to be suffering from perforation turn out to be suffering from appendicitis, while in another case a lad who was suffering from abdominal symptoms, attributed to his having been run over, proved to be suffering from typhoid fever.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Pathology.

Meeting held December 5th, 1902.

E. J. **McWeeney**, M.D., President, in the Chair.

Dr. **Earl** showed a case of

SARCOMA OF THE LEFT SUPRARENAL CAPSULE,

with secondary growth in thorax, involving the right lung, the pericardium, and right auricle, and causing narrowing and thrombosis of the superior vena cava.

The **President** wished to know whether the material found inside the superior vena cava was in the nature of a thrombus, and if so whether Dr. Earl regarded it as an embolus or as something which grew from the ung and auricle into and through the walls of the vein, *i.e.*, whether it was a thrombus due to loss of vitality, or to growth of the tumour? He said it would be interesting to study the relations of the tumour to the walls of the vein and of the auricle, as to whether it infiltrated these structures or not.

Dr. **Earl**, in replying, said that he looked upon the material as an ordinary thrombus, due to slowing of the circulation and infiltration of the vein walls. He made no microscopic examination of it, but it was partly white, partly red, and probably did not contain any tumour tissue.

Drs. **Maunsell** and **Earl** showed a case of

CANCER OF THE TRANSVERSE COLON.

There was a small polypus in the neighbourhood of the tumour, which presented histological characters which appeared to indicate malignancy.

Professor **O'Sullivan** said he was inclined to regard the polypus as an adenomatous growth due to irritation of the malignant growth. He had seen a case in which there was a row of these lying round the cancer.

The **President** said it would be interesting to find two malignant tumours existing independently of each other, for example in the bowel. If he had seen the specimen without previous knowledge of it he would have thought it more than a simple tumour. He thought it was a cancer of the bowel in its very initial stage.

Dr. **Earl**, in replying, agreed that if it was malignant it was a very early stage. Dr. O'Sullivan had mentioned a case in which there was a ring of these growths round a cancer, and that he considered them innocent, but he might as well have considered them malignant if they had a structure similar to that he showed to-night. He said that two independent malignant processes did sometimes occur; there might be a cancerous tumour on one wall of the œsophagus and another on the other wall with healthy tissue between. The question of the changes of cells was of most importance in connection with curettings of the uterus. Though the structure of the mucous membrane of the intestine was not the same as that of the uterus, the same general laws held good.

Dr. **Earl** showed a case of

DROPSY OF THE GALL-BLADDER

due to obstruction of cystic duct by a gall-stone.

Mr. **Arthur Benson** read the notes of a case of

INTRA-OCULAR TUMOUR

which occurred in the left eye of a child, æt. 3. Six months before admission to St. Mark's Ophthalmic Hospital the creamy white reflex from the pupil was noticed, but there was no pain apparently. On admission the cornea and lens were perfectly clear, the iris was discoloured and vascular, with numerous vessels visible on its surface. The vitreous chamber was completely filled by a creamy coloured tumour which had moulded itself against the posterior surface of the lens. The tension of the eye was · + 2; this, added to the appearances, made the diagnosis of pseudo glioma very improbable, whilst the age of the child was against sarcoma of the choroid, so that glioma of the retina was the most probable diagnosis. Enucleation was done and the globe examined by Dr. Neville, who reported as follows:—"On microscopical examination the tumour shows the characters of a round-celled sarcoma, of a markedly cylindromatous type. The tumour-cells form well-marked sheaths for many of the vessels, in the neighbourhood of which the cells are both larger and stain better than they do outside the range of immediate nutritive supply. There are areas of hæmorrhage, and also semi-necrosis, where nuclei stain feebly, and scattered through the mass are many areas of calcification, some smaller vessels having completely calcareous coats. Examined unstained the cells do not show any abnormal pigmentation. Mallory's glia-stain fails to show any gliomatous structure, and the sections so far made do not help to solve the question of the origin of the tumour. The remaining part of the tumour is being decalcified."

The **President** fully agreed in not giving the name glioma to this tumour. In most of these cases of intra ocular tumour springing from the retina, the characteristic spider cells were not seen, even in staining by the Golgi method. True glioma of the retina was very rare. He had heard of a case of a child, æt. 4, who was attacked by this disease in both eyes, and from each of them there was a tumour projecting as large as a closed fist of an adult.

Dr. **EARL** could not agree with Drs. McWeeney and Neville in calling these growths sarcomata. They could be traced to the retina itself, and our ordinary view of sarcomata was that they were connective tissue growths, while there was very little of this tissue in the retina. Again, in ordinary glioma of the brain the spider cells were not found with any readiness, and the growths there also frequently resembled sarcomata. He considered neuro-epithelioma the best term for such tumours as Mr. Benson showed.

Professor **O'SULLIVAN** said that the tumour seemed to consist of two parts, one surrounding the vessels and consisting of large cells, and the other consisting of small round-cells corresponding in appearance to those found in what is called glioma of the retina. He did not see why these tumours should be called gliomata, considering they were derived from the inner molecular layer of the retina. The different characters of the two parts of this tumour seemed to him to make the diagnosis unusually complicated and difficult.

The **PRESIDENT** said there were certainly two kinds of cells of different sizes in the tumour, one with large nuclei packed close together and little protoplasm, the other with very small nuclei and no protoplasm. The nomenclature of these tumours was very unsatisfactory. There were two standpoints to consider them from; the morphological and the histogenetic. Morphologically these tumours were to be classed with small, round-celled sarcomata. Histogenetically they might belong to the epithelial class of tumours. Whether they originated from epiblastic sources was open to discussion. Supposing those cells were of epithelial origin, morphologically they did not resemble epitheliomata; they were sarcomata.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

CLINICAL MEETING.

MEETING HELD DEC. 5TH.

MR. C. B. KEETLEY showed a patient who had been sent into hospital three weeks ago with a rupture of the ligamentum patellæ. The patient was a middle-aged man. Five weeks had passed since the accident. The ruptured ends were brought together with silkworm gut. A piece of stout silver wire was inserted through the patella and the tubercle of the tibia, as a temporary ligamentum patellæ. At present, three weeks after the operation, the patient can walk and extend the knee painlessly. The silver wire would be removed in two or three months.

Dr. **CLIPPINGDALE** wished to know whether, in passing the wire, Mr. Keetley was able to keep outside the cavity of the knee-joint.

Mr. **GARRY SIMPSON** showed: 1. A child, in apparently good health, who last summer suffered from no less than eighty-five tuberculous abscesses of the skin. The deposits under the skin were about the size of the kernel of a hazel-nut. The nodules were scraped out with a Volkmann's spoon; the only other treatment was open air and good food. 2. A man who had recovered from tetanus. A rusty nail perforated the sole of his foot for about one inch. The wound was irrigated with 1 in 1,000 perchloride solution; but fourteen days after the injury the man developed tetanus. Mr. Bidwell injected anti-tetanic serum into the posterior portions of each second frontal convolution. Mr. Garry Simpson suggested that in such cases serum should be injected immediately after the injury without waiting for symptoms of tetanus, and that oxygen should be forced into the wound. 3. A child who had got its tongue between the cog-wheels of a clockwork engine. With the assistance of a plumber the machine was unsoldered and the tongue released. The portion of the tongue caught in the cog-wheels subsequently sloughed. 4. A patient who, in falling from a pear tree, ran a piece of wood for some inches under his scalp. By means of antiseptic precautions, drainage, and free oxygen to the wound, a complete cure resulted in a few days.

Dr. **CLIPPINGDALE** said that in the child with multiple abscesses, in addition to the suggestions of tubercle, syphilis, or pus infection, farcy might be a possible cause.

Mr. **ATKINSON** doubted if the case were one of tubercle.

Dr. **WHITFIELD** agreed with the diagnosis of tuberculosis. The tuberculides probably arose as bacillary emboli from some central focus. These emboli were probably either bacilli of extremely low virulence or dead bacilli. This would account for the mildness of the symptoms, and the negative result of inoculation experiments. Probably the child has had, or still has, a tuberculous focus, possibly in the bronchial or mesenteric glands.

Mr. **KEETLEY** suggested, with reference to the case of tetanus, that all punctured wounds, with the possibility of infection by tetanus, should be opened up and disinfected in some such way as that suggested by Dr. Garry Simpson.

Dr. **SEYMOUR TAYLOR** showed two cases of mitral stenosis, accompanied in each instance by mitral regurgitation. The first patient, a smith, æt. 40, had had rheumatic fever. The murmur occupied the middle third of the diastolic period, and was limited to the site of the apex beat. In this case the administration of digitalis was followed by good results, the drug being specially indicated by the irregular pulse and the existence of chronic bronchitis. In the second patient, a clerk, æt. 25, who had been an athlete, there was no history of previous acute rheumatism. The murmur occupied the late diastolic period (presystolic). Great improvement resulted from rest without digitalis or other cardiac tonics.

Dr. **WHITFIELD** showed a woman, æt. 36, with a symmetrical scarring eruption over the deltoid region in both arms. The disease commenced twenty years ago, with no history of injury. There were one or two similar smaller patches on the right buttock. The smaller patches were simply white atrophic spots on the skin, and were said by the patient to constitute the early lesion. The older patches consisted of a band of white atrophic skin surrounded at either end by smooth red infiltration. This showed no claw-like processes. Microscopically, a small piece of this margin showed a formation of new fibrous tissue in the middle of the corium, not affecting the papillary layer, and containing practically no elastic fibres. Dr. Whitfield believed the disease to be an unusual form of sclerodermia, but others regarded the case as one of keloid. However, the scar formed after excising the piece of infiltrated edge showed no sign of becoming keloidal.

Mr. **PATON** showed a woman, æt. 58, who was operated on in September of this year for chronic intestinal obstruction associated with considerable loss of weight. An incision in the middle line of the abdomen revealed many omental adhesions, but on separating these a small annular constriction was found at the splenic flexure of the colon. A second incision was made immediately over this, 3 in. of the gut were excised, and the divided ends were united by two continuous sutures. The abdominal wounds were completely closed, except for a small gauze drain. The patient recovered without any trouble, except a diarrhœa, which was very difficult to stop. She has since almost regained her normal health, and has put on nearly a stone and a half in weight.

Dr. **A. E. RUSSELL** showed: 1. A case of syringomyelia of the cervical and upper dorsal regions of the cord. The patient was a joiner, æt. 50. He had well-marked neurotrophic arthropathy of the left wrist and carpal joints; also creaking of the shoulders. In addition, there was typical dissociative anæsthesia of both hands and arms, neck, scalp, and trunk, down to the fifth thoracic segment. Tactile sensation was intact, but painful stimuli and heat and cold were not appreciated. There was also considerable atrophy of the intrinsic muscles of the right hand. The knee-jerks were greatly accentuated. The combination of muscular atrophy, dissociative anæsthesia, and trophic joint lesion presented a complete picture of syringomyelia. 2. A man, æt. 34, who contracted syphilis ten years ago. Five years ago he suffered from gastric crises; after eighteen months these were succeeded by weakness of the legs. He also had laryngeal crises, lightning pains in upper and lower limbs, and marked ataxia of arms and legs. He had been treated by Mr. McAdam Eccles for an enormously distended bladder and urethral stricture. The chief feature in the case was the marked muscular atrophy in the whole of the lower limbs. This is a rare phenomenon in tabes dorsalis. Probably the condition was due to atrophy of the cells in the anterior cornua, for there was practically no sensory disturbance such as might be expected if the lesion were one of the peripheral nerves.

With regard to the case of tabes dorsalis, Dr. **Seymour Taylor** thought that there must be some predisposing factor besides syphilis. The disease is comparatively rare in women. In his opinion the man who indulged in excessive sexual excitement, if he contracted syphilis was likely to become the victim of locomotor ataxia.

Dr. **Mallam** asked for suggestions as to the treatment of tabes dorsalis, and also wished to know the cause of the excessive muscular wasting in the patient shown.

Mr. **Atkinson** agreed with Dr. Seymour Taylor as to the twofold cause of the disease.

Mr. **Armour** pointed out the entire loss of sexual desire on the part of the sufferer from tabes.

Mr. **Lloyd** asked for Dr. Russell's opinion on injury as a cause of tabes dorsalis.

THE LARYNGOLOGICAL SOCIETY OF LONDON.

Meeting held Friday, Dec. 5th.

The President, **Mr. E. Cresswell Baber**, F.R.C.S., in the Chair.

Mr. W. H. R. **Stewart** showed a case of nasal deformity, and one of strumous ulcers of mouth and tongue.

Mr. F. J. **Steward** showed a specimen of malformation of the œsophagus, obtained from an infant five days old. The child had been quite unable to swallow, milk being regurgitated after five minutes. There was complete obstruction five inches from the gums. The specimen showed dilatation of the upper portion of the œsophagus which ended in a blind extremity about an inch above the bifurcation of the trachea. The lower portion of the œsophagus communicated at its upper end with the trachea.

Mr. **Hunter Tod** showed a case of laryngitis hypertrophica in a girl, æt. 21, following prolonged nasal trouble.

Dr. **Scanes Spicer** gave a lantern demonstration on some recent investigations on the normal fluctuations of air pressure in the upper respiratory tract and the effect on these fluctuations of nasal obstruction artificially produced. He suggested that a naturally wide rima with the consequent diminution of normal pressure fluctuations and lessened rhythmical stimulus to circulation in the blood-vessels, and so lessened nutrition of the walls, was the explanation of the origin of atrophic rhinitis.

Dr. **Logan Turner** showed a new series of anatomical preparations demonstrating the artificial production of œdema of the larynx. Injection of carmine gelatine had been made into the loose submucous tissues under varying amounts of pressure; the consequent swellings closely simulated the conditions met with clinically in œdema. He also showed a case of abnormal narrowing of the larynx and trachea, probably congenital in origin. The epiglottis was of infantile type, and the whole upper laryngeal aperture was considerably narrowed and the trachea flattened from side to side throughout its entire length. Dr. Logan Turner further showed a specimen of malignant stricture of the upper end of the œsophagus from a woman, æt. 58.

Dr **Herbert Tilley** showed a case of advanced epithelioma of the epiglottis, with secondary infection of the cervical glands, with the object of illustrating the relief obtained by removal of the primary growth through the mouth. Attacks of dyspnœa and extreme difficulty in swallowing were the chief symptoms. A radical operation was evidently quite out of the question, but Dr. Tilley had removed the primary growth at several sittings by means of Krause's and Watson Williams' cutting forceps. The relief of the symptoms had been extraordinary.

Dr. **Wyatt Wingrave** showed a case of laryngeal growths in a man, æt. 50, which had been previously shown to the Society last April, when no definite diagnosis was arrived at. The symptoms had improved, but the growths had distinctly increased in size.

Dr. **Dundas Grant** showed a case of paralysis of the abductors of the vocal cords in a youth shown at the last meeting. He thought there was some improvement in the paralysis of the abductors. Dr. Grant also showed a case of comparative hemi-anæsthesia in a young female with subjective nasal obstruction on the affected side. In the discussion which followed, some doubt was expressed as to whether there was not real nasal obstruction due to collapse of the ala. Dr. Grant further showed a case of increasing dysphagia of six months' duration in a middle-aged man, probably due to pharyngeal epithelioma. On examination, a growth could be seen projecting from the wall of the pharynx, and hiding the posterior part of the ary-epiglottic folds. The patient had been on iodide of potassium with subjective relief, but no visible change in the growth.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Meeting held at Sheffield, November 21st, 1902.

Dr. S. Buckley, President, in the Chair.

PRIMARY TUBERCULOSIS OF THE OVARY.

Dr. J. E Gemmell (Liverpool) related the case of a woman, æt. 26, married two and a half years previously, but sterile. Three months after marriage she was treated for pelvic peritonitis which left some thickening on the right side of the pelvis. Three months ago the cervix was dilated, and the uterus curetted with a view to relieving the dysmenorrhœa and sterility, and at that time only a little thickening was detected on the right side, although the patient had complained of pain on this side for some time. Menstruation had been regular but painful, the loss being normal in amount. Dr. Gemmell examined the patient under an anæsthetic and found the uterus fixed. The right ovary, enlarged to the size of a fist, was hard and fixed. The left appendages felt small and adherent to the pelvis. The diagnosis lay between an adherent solid ovarian tumour and a tubo ovarian abscess. The abdomen was opened. The omentum was adherent to the abdominal wall, and the coils of intestine were matted together and adherent to the tumour. The latter also adhered to the back of the broad ligament. In removing the tumour its wall was torn, and fœtid, thick, curdy, jelly-like pus escaped. The left ovary was caseous and disorganised, the tube contained a plug of calcareous material, and its fimbriated end was closed. There were no signs of miliary tubercle on the peritoneum and no pyosalpinx, and there had been no evidences of tubercle in any other part of the body. On examining the specimens the right tube was adherent to the ovary, and the ostium closed. The tube was free from pus. The ovarian stroma was riddled with foci of suppuration. The pus contained putrefactive organisms and staphylococci, but no streptococci, gonococci or tubercle bacilli were detected. Microscopical sections showed well-marked giant-celled systems. The disease being localised to the ovary and fimbriated end of the tube only suggested the probability of the disease being a primary ovarian tuberculosis.

Mr. R. **Favell** (Sheffield) described a case of "Cæsarean Section for Labour Obstructed by an Ovarian Dermoid." The patient, æt. 35, was in her sixth pregnancy. Mr. Favell detected the tumour four years ago, but the patient declined operation. Two years later the fifth labour took place, and was terminated by version, the doctor in attendance having difficulty with the tumour. The sixth labour coming on, the doctor found the tumour had increased and sent the woman to Mr. Favell at the Jessop Hospital. The tumour was found tense and bulging, and occupying the pelvis. The abdomen was opened, and as the tumour was fixed by dense adhesions in Douglas's pouch, Cæsarean section was first performed and then the tumour removed. The child was living, and the mother made a good recovery. The cyst contained much hair and sebaceous material.

Dr. W. **Walter** (Manchester) gave particulars of a case of "Ovariotomy performed on a patient who was four months pregnant." The cyst was the size of an ostrich's egg, and had a fairly long pedicle, which was twisted once, but which had caused no evidence of strangulation. The pedicle was secured as far as possible from the uterus in order to lessen the danger of abortion. The patient did well and the pregnancy went to full term.

Specimens, Etc.

Dr. **Sinclair White** (Sheffield) showed: 1. A large fibroid uterus removed by pan-hysterectomy from a patient, æt. 39, who had suffered for four years from profuse menorrhagia. 2. An ovarian fibroma weighing seven pounds from a patient, æt. 45. The adhesions were universal, and a small portion of intestine required resection. 3. A Fallopian tube removed from the sac of an irreducible femoral hernia. 4. An unruptured tubal gestation removed from a young woman who was thought to be suffering from appendicitis. Recent peritonitis was noted around the sac. 5. A uterus containing a six weeks pregnancy, and a large, soft, rapidly-growing fibroid. The fibroid closely resembled an interstitial pregnancy at the time of operation. All the patients recovered.

Dr. W. **Walter** (Manchester) showed a "Uterus and Occluded Tubes" removed per vaginam from a patient suffering from pelvic peritonitis. Owing to dense adhesions complete removal of the ovaries was impossible. Hysterectomy was therefore performed, as being less dangerous in this particular case than persistent efforts at completing a double oöphorectomy.

Mr. R. **Favell** (Sheffield) showed large "Fibroid Polypus of the Uterus weighing three pounds eleven ounces," which had become extruded from the vagina the day before its removal. The pedicle was long, and there was no inversion of the uterus. The perineum was not injured.

The cases and specimens were discussed by the President (Dr. Buckley), Drs. Lloyd Roberts, A. Donald, J. E. Gemmell, W. Walter, R. Favell, and E. O. Croft.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Meeting held November 20th, 1902.

The President, **Dr. John Robertson**, in the Chair.

Dr. D. Burgess showed a case of "Disseminated Sclerosis."

Mr. R. **Favell** related a case of "Cholecystotomy."

Mr. **Arthur Connell** showed the following cases:—

A baby.—Amputation of sacral teraboma six days after birth owing to the most dependent part becoming exceedingly thin, and on the point of ulceration, very broad base. Contained a small portion of bone, a section of which was shown and found to be of the Haversian type.

M. L., æt. 46.—Recurrent inoperable scirrhus carcinoma of left breast. Primary growth removed six years ago. Recurrence last year, two large tumours, one situated at sternal end of clavicle, the other partly over sternum, and involving second interspace, with considerable œdema of the arm. On August 25th, double oöphorectomy was performed, and six weeks later shrinking began in the tumours, and with it the rapid disappearance of pain and œdema. Patient now free from pain and sleeping well. Is having thyroid feeding.

W. M.—Ruptured duodenal ulcer, with subsequent gastro-jejunostomy (already reported in the *Lancet*, September 6th).

W. L., æt. 16.—Ruptured ilium, from a fall on to the kerbstone, striking theabdomen. Patient seen by me twenty-four hours after the accident, and immediately operated upon. Wound in gut easily found on right side, owing to relative dulness on that side. Operation October 11th, 1901. Patient working in a coal pit again.

Dr. **Arthur Hall** showed: 1. A case of folliculitis of both legs, due to frequent salivation of the trousers by oil during the course of his work, the so-called oil acne; 2. A case of dermatitis artefacta in a young girl, simulating a patch of ringworm on the right forearm. Since completely protecting the patch by zinc gelatine, two new patches have appeared on the leg.

Mr. **Snell** introduced a young woman whom he had treated for severe ectropion of the upper eyelid by transplantation of a large graft. The portion transplanted was taken from another patient's eyelid who was under treatment at the same time for superabundant folds in the eyelid which were occasioning ptosis. The graft measured 1½ ins. long by ¾ in. wide. Most of it had lived and the result was excellent.

Dr. Gwynne read a paper on the treatment of certain cases of "Infantile Paralysis by Arthrodesis." He illustrated the value of the treatment by the notice of two cases thus treated, both with excellent results. One was a case of paralysis of right leg involving all the muscles that control the knee and ankle; the other was a case of calcaneo-valgus of a severe type. The patients were both able to walk without the aid of any support or stick, and their appearance did not suggest any deformity beyond the stiffness incidental to the treatment. He claimed a more extended use of this method of treatment.

Dr. **Seeley** read a paper on the

DIETING OF TYPHOID.

1. The ideal conditions of hospital do not exist in private practice, especially among poorer classes. Strict dieting cannot therefore be, and is not, adhered to. 2. The mortality in private practice is less than that of hospital (Osler gives 8½ per cent. for former to 13½ per cent. for latter). 3. Typhoid (the word "enteric" ought not to be employed) is not a local disease of intestine, but may occur without marked, or even any, intestinal lesion whatever. 4. The majority of cases are mild, of no more account than scarlatina or measles (perhaps the type of typhoid is changing and becoming milder). 5. Perforation and relapse are the results of the typhoid process. There is not one particle of evidence to show they are due to giving solid food. 6. As the result of giving good nourishing food patient's condition is more satisfactory and convalescence shortened.

CORK MEDICAL AND SURGICAL SOCIETY.

Meeting held Wednesday, December 10th, 1902.

Dr. J. Cotter, Vice-President, in the Chair.

Case of Excision of Cæcum for Carcinomatous Growth.—Dr. T. **Gelston Atkins** showed a man, æt. 32, on whom he had performed excision of the cæcum and the adjacent portions of the large and small intestines for a carcinomatous growth. The patient had lost a good deal of flesh for the preceding four or five months, and a hard tumour about seven inches long and four inches broad could be detected in the right lumbar region, extending into the umbilical, hypogastric, and right iliac regions. Having cut down on the tumour, he clamped the adjacent portions of the bowel, removed the entire mass, invaginated the cut ends of the intestines, and effected a lateral anastomosis between the ileum and the transverse colon. The patient made a rapid recovery from the operation. The growth proved to be of a carcinomatous nature, with a good deal of fibrous tissue between the cancer cells. No enlarged glands could be detected in the abdomen, but, of course, the ultimate prognosis in the case was unfavourable.

Dr. **Henry Hobart** thought a side-to-end anastomosis would effect a saving of time in such an operation.

Dr. **Cotter** was of opinion that the use of Mayo Robson's bobbin in these cases expedited the operation.

Dr. **Atkins**, in reply, said that the sectioning of the mesentery involved in end-to-end and side-to-end anastomoses generally gave rise to a certain amount of hæmorrhage, which he had often found it difficult to completely arrest. Since seeing Doyen repeatedly making use of the lateral form of anastomosis, he had followed that procedure with the best results.

Two Cases of Gastro-Jejunostomy.—Dr. **H. R. Townsend** showed two patients on whom he had performed gastro-jejunostomy. One patient, a female, æt. 25, had suffered from severe ulceration of the stomach from time to time since 1894, and had been under ordinary medical treatment over and over again, with only temporary benefit. The other patient, a man, æt. 27, had an enormously dilated stomach and suffered almost constantly from profuse vomiting. In his case also the ordinary treatment had been followed without success for several years. Several months had elapsed since the operations, and both patients are now able to take all kinds of food, and are free from all symptoms of gastric trouble.

Case of Splenic Anæmia.—Dr. **Norman Townsend** showed a girl, æt. 22, suffering from splenic anæmia. The patient had never menstruated, her mammæ were undeveloped, and there was complete absence of hair under the axillæ and over the pubes. The spleen extended to the middle line in front, and could be felt three inches below the umbilicus. The blood was of the chlorotic type, the deficiency in corpuscles being but slight, while the colour-index was only 0·7. There was no excess of leucocytes.

France.

[from our own correspondent.]

Paris, Dec. 14th, 1902.

Appendicitis.

At the meeting of the Société de Chirurgie, M. Regnier said that he was a partisan of temporisation, which had given him excellent results. Out of seventy-one cases which he treated by expectation, fifty-nine recovered by medical treatment alone, and only two died.

He was absolutely convinced that if the treatment by ice and opium were instituted at the outset, very few grave cases of appendicitis would be observed.

M. Michaux said that out of fifty patients suffering from appendicitis he had seen this year, forty-five were operated, of which thirty-nine in the interval and six during the acute stage. All the former did well, but two of the latter succumbed. Four others were so well satisfied with the medical treatment that they refused an operation. He also became more and more a partisan of expectation and medical treatment (refrigeration).

M. Potherat did not operate after a slight attack nor where the abscess had opened into the intestine, unless there remained behind a certain amount of induration. Beyond these two conditions he operated, but as much as possible in the interval. He was only a partisan of immediate operation when the diagnosis was made at the onset. In his hospital service he had operated during the last two years on 115 cases of appendicitis, of whom seventy-nine were during the period of quiescence and were all successful, and thirty-six during the attack, and of these eleven died.

Beer Yeast.

The properties of yeast as a microbicide in certain eruptive affections such as furonculosis, small-pox, chicken-pox, or erysipelas, are receiving the attention of many therapeutists. Dr. Conche, of Lyons, has published an article on the subject as regards the treatment of small-pox and chicken-pox, and for which he obtained very satisfactory results. Of eight cases, three of whom were small-pox, he remarked that the fever abated rapidly, and the eruption did not come to maturity, consequently there was neither suppuration nor the subsequent formation of boils so frequently observed after these affections. He gave the fresh beer yeast in beer or in some other liquid, masking the taste of the yeast in doses of three tablespoonfuls a day. In six cases of erysipelas of the face Dr. Abouchard administered prepared yeast (dry) in doses of three teaspoonfuls a day and found that under its influence the fever rapidly diminished and the inflammatory zone did not extend. Prof. Maine, of Paris, systematically treats pulmonary affections such as pneumonia in the aged and chronic bronchitis with beer yeast, while Dr. Lardier took it for the subject of his *these*, and in which he proved that in the bronchial catarrh of old people the employment of beer yeast produced a rapid decrease in the expectoration, and finally a complete cure. He tried it also with success in pneumonia after the acute stage had passed. Perhaps the dry form as prepared by chemists is more agreeable to the taste than the fresh yeast; in any case it is quite as efficient.

Germany.

[from our own correspondent.]

Berlin, December 13th, 1902.

At the Society of Charity Physicians Hr. Jolly showed and described four cases of

Tuberculous Disease of the Spinal Cord.

In the first case there was spastic paralysis of both legs from pressure on the cord. In the second case, in which similar symptoms presented, the symptoms had receded in consequence of long-continued treatment by extension so that no trace of disturbance in walking existed any longer. The third case, of a similar nature, was that of a patient who had been affected from her first year of life, in which there was a rachitic curvature this one also, although there had been complete paraplegia could now run well. The speaker remarked that the functional disturbance of the cord did not necessarily correspond to the curvature of the spine. Generally it was not a compression, but an exudation between the dura and the bone, or in the membranes, and changes in the substance of the cord. There was frequently only a collateral œdema, but the affection was often myelitic in its nature, the latter generally in connection with bladder disturbance, with loss of sensibility and mobility. This question, so important in point of prognosis, was often very difficult to answer. The preparation of the fourth case was shown, in which, in spite of flaccid paraplegia of both legs, the patellar reflexes persisted up to the death of the patient. The case was one of tubercle of the substance of the cord, in which, as the retained sensibility showed, some few fibres remained uninjured.

Hr. Köning remarked that pressure paralysis of that kind was rare, but it might take place, and operation was justifiable only in rare cases.

Hr. Jacob observed that in such cases, with extension treatment, recovery was late, but rapid when it did begin.

At the Hufeland Society Hr. Boaz spoke on

CARCINOMA AND DIABETES.

The subject had been extensively discussed in French literature, but far less comprehensively than in German. Griesinger, in 200 cases of diabetes, had not met with an undoubted case of carcinoma. Naunyn admitted the simultaneous occurrence of both diseases, and had collected cures. Cupler had found sixty-eight cases in which carcinoma of the more varied degrees was co existent along with diabetes. The speaker himself since 1896 had observed twelve cases of carcinoma in 366 of diabetes. In seven the disease affected the rectum, two the œsophagus, two the stomach, and one the liver and omentum. All the patients were males. Cupler admitted that the predisposition was less in women than in men.

How long the diabetes existed before the carcinoma was never certain. The period varied between seven months and fifteen years. The amount of sugar was from 1 to 5 per cent. Aceton and acetic acid were met with only once. The youngest patient was thirty-nine and the oldest sixty-five. These cases were operated on. One patient survived the operation, and no complications occurred. Two years had since elapsed, and the patient was still well. The second patient, who still had sugar in the urine, died of diabetic coma a few days after the operation. A third patient died nine months after operation of progressive cachexia.

Views as to the course of carcinoma in diabetes differed widely. Tuffier came to the conclusion that carcinoma in diabetes grew very slowly, as the conditions as to nourishment were so unfavourable. In contrast to this were the views of Cupler, Gilbert, and Weill, who had seen extraordinarily rapid progress of the disease even when conditions as to nourishment were unfavourable. The speaker agreed with these views with this limitation, that there was a difference between the course in active and in passive diabetes. Only in the former case was the course of carcinoma rapid. In the second case the course was extremely slow.

The diabetes was primary and the carcinoma secondary and there was a decided connection between the two. Two classes of cases could be distinguished. In the one, on carcinoma being established, a surprising tolerance of carbohydrates appeared, in other cases the diabetes continued to the end. In the second class also the diabetes appeared to be checked. In some cases the carcinoma was antagonistic to the sugar, in others the formation of sugar continued unchanged. Why this was so did not appear. The relative infrequency of carcinoma in diabetes did not support the prevailing view that carcinoma was due to animal foods.

Operation for carcinoma in diabetics did not come under the general rule as to danger. The only question was, whether a radical operation was practicable, and in spite of the danger of operation, it ought to be advised so long as there was neither nephritis nor cardiac weakness. It had been thought that an extinct diabetes could not be dangerous, but this was an error. A diabetes that had disappeared for a year might be lighted up afresh by operation under chloroform narcosis, and lead to diabetic coma. Hoffa and Landau, among others, had reported such cases.

In case of manifest diabetes no physician could forget the dangers. But even here operation might have good results. Carcinoma patients should have their sugar removed before operating, if this did not take too much time. Operation during acetonuria was naturally more dangerous.

As regarded the treatment of carcinoma-diabetes, each case must be considered individually. It was certain that absolute removal of sugar must not be striven for, as the carcinoma itself would be unfavourably affected by this, and generally the patients were advanced in years, when diabetes was no longer as dangerous.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, December 13th, 1902.

ABDOMINAL SPASM.

AT the "Gesellschaft fur innere Medicin" Bum presented a patient, æt. 22, who formerly suffered from severe attacks of abdominal spasm, flexor as well as extensors. About two years ago she suffered from constipation with commencing pain which led in a short time to a kyphotic condition of the body associated with great pain in chest, back, and head. Purgatives of all kinds were employed without effect. It is worthy of note that even after the pains had subsided the muscular spasm persisted, notwithstanding the efforts to engage the attention, or require her to perform some peculiar movement, such as moving backwards on the knees. Percussion of the abdomen revealed a dull area over the descending colon, quite tough and hard, that could not be kneaded, which is often found in characteristic chronic spastic constipation. Bum thinks this the basis of the functional form of atony that leads to habitual spastic constipation. On relieving the spasm with narcotics the constipation was removed and the patient cured. In neurasthenic males a similar state of affairs exist.

HÆMORRHAGIC DIATHESIS.

Reiter showed a young locksmith, æt. 28, who since he was eight years of age suffered at varying periods from pain and swelling of the joints. This phenomenon often appeared without pain or any possible injury, while the joint in both cases was quite movable without any increase of the pain. Sometimes there was fever associated with the swelling, and sometimes there was not. The heart during the attack was unaltered and normal, while the general health seemed always good. While in hospital on one of these occasions his teeth began to bleed profusely and at the same time he became extravasated with large patches under the skin. The history of the family is remarkable for hæmorrhagic attacks. Repeated hæmorrhagic effusions into the joints have so interfered with the movement that the patient cannot bend them sufficiently to carry on his work.

The differential diagnosis was from articular rheumatism and fungoid growths. The former might be discarded as inconsistent with the symptoms, while the latter is supported by experiments which Konig performed with similar symptoms to remove the fungus. No sooner had he opened the swellings in two of the cases than incontrollable hæmorrhage commenced that brought about death within an hour.

In the case related operation has never been contemplated, but rest in bed, with compression and dry warmth has done much to reduce the fungoid growths.

Bullet Lying in Cardiac Wall.

Kienböck showed a patient, æt. 26, who in the beginning of December last year attempted suicide by shooting himself in the right temporal region and heart; the second bullet deviating so that it finally lodged in the posterior cardiac region. Twenty-four hours after the occurrence he recovered from the fainting condition which the first effect of the bullet produced, after which there was a slight rise of temperature with hæmorrhage from the lung, and constant pain in the head. The wound of the head healed up rapidly without any bad symptom. In a short time a systolic murmur appeared, but no effusion into the pleura was observed.

On account of the increasing pain in the head the wound was trephined with the hope of securing the bullet which was ultimately effected.

The condition of the heart up to this time might be described as dulness normal, apex beat in fifth intercostal space within the mamillary line with a broad high systolic area of vibration. There was also a loud, somewhat rough systolic murmuring over the region of the mitral valve which could be heard over the upper part of the heart. The second pulmonary sound was accentuated, and with the rays, and turning the patient half round the bullet could be observed on deep inspiration in the posterior wall of the heart about two centimetres above the diaphragm and in front of the spinal column. The bullet was moved regularly synchronously with the movement of the right half of the heart opposite the ninth dorsal vertebræ.

The second bullet seems to have first passed horizontally through the lung towards the back, where it struck the rib, then rebounded against the side of the body of the ninth vertebræ, and finally lodged in the posterior wall of the heart.

We now come to the coincidence of the mitral valve lesion with the accident, which may be accounted for by the lesion occurring at the instant of cardiac systole when the organ is in a state of complete tension, and any sudden strain would snap the finer fibres.

Braun said he could hardly agree with Kienböck on the theory of the mitral rupture, as the wounding of the cardiac wall without any lesion of the valves whatever will produce a murmur from the imperfect closure of the ostium. We have many cases on record where injury to the base of the heart or its muscular sheath produced murmurs during life although the valves were found to be uninjured at the post-mortem, and others in which when recovery occurred the murmur has disappeared. Barnard observed this lesion in experiments bearing on the integrity of the pericardium. The tricusped was often affected in the same way.

Schrotter thought the history of the case was against Kienböck's theory of rupture by compression, as the path of the projectile was among soft tissue, and did not require to rebound as assumed. Again, to support Braun's theory he must assume that some of the papillary muscles of the heart must have been wounded in the wall of the cardia to produce the insufficiency.

Braun retorted by saying that such an assumption was quite unnecessary, as it has been amply proved by experiment that any interference with the venous supply of the ostium will immediately prevent the valves from perfectly closing the orifice.

Pharmacists on Strike.

The *employes* in the apothecary shops of Cracow Lemberg, and other Galician towns have gone out on strike. They demand higher wages and shorter days. These demands having been refused, the work has had to be attended to by the proprietors.

Winter Health Resorts.

THE CANARIES AND MADEIRA.

[FROM OUR SPECIAL CORRESPONDENT.]

Madeira.—Owing to the exigencies of journalistic space my letter on a recent visit to the Southern Islands was broken off on leaving Grand Canary, and I propose to complete it now with a brief description of Madeira, which, although but a day's journey distant from the Canaries by the fast steamers, differs nevertheless, in almost every particular. It is not my purpose to describe the island as in guide books, nor is it necessary to go into particulars from a strictly medical point of view; this has already been done by Dr. Gordon, Dr. Symes Thompson, and others. Having had to travel for health's sake, my object in penning these brief notes is in the hope of imparting information to the over-wrought practitioner, who can spare a month at this season that will tempt him to escape from his thraldom for the nonce, to enjoy the exquisite beauties of these islands at very moderate cost.

Funchal is the port of call for Madeira, on arriving at which the visitor will be at once struck at the absence of the ordinary wheeled conveyances and the camels so familiar in the Canaries, passengers and their luggage being taken from the shore in *carros* drawn by bullocks up steep lanes to their destination. Several good hotels will be found here at various elevations and at moderate charges. The distinctly Eastern character of the inhabitants and surroundings of the Canaries are not met with here, but, like the camels, are conspicuous by their absence; the rows of single-storied flat-roofed houses have vanished, and in place thereof are two and three-storied houses, attractively built of blue basaltic stone, villas being obtainable for the winter to suit all purses. Within five or six days after leaving the murky atmosphere of some great town in the British Isles, one finds one's self installed midst everything that is beautiful to the sight and agreeable to the senses generally; flowers bloom in midwinter in tropical luxuriance; thus placed, the traveller must be of a severely selfish nature who does not sympathise with those who by force of circumstance or habit are compelled to winter at home. Locomotion for distances is usually on horseback, or the visitor is carried by hammock men if preferred, as in India, a novelty to which one becomes readily accustomed. Here the temperature differs but slightly from that at the Canaries, the mean varying only from 61°F. to 64°F. during the five so-called winter months, but there is more rain, consequently the hygrometric condition is somewhat more favourable in cases of chronic affections of the lungs and air passages; the moist, mild atmosphere with its absolute freedom from dust also forms an excellent sedative in bronchial and asthmatic complaints. As Funchal is protected by a rugged mountain range of 6,000 feet the town is entirely sheltered from the north-east winds.

Cold is not experienced; snow is never seen except in the distance on the mountains, and from here all excursions are taken. The native population are exceedingly polite to strangers, but begging is somewhat of a nuisance here as in Italy, and the authorities might improve matters by rendering the custom house less annoying to strangers.

The route is from Liverpool or Plymouth, the majority of the fast mail steamers of the Elder, Dempster lines sailing from the former direct, and excellent accommodation will be found on board these boats. I may add that the Canaries and Madeira cannot be done within the month if the passage out and home be taken as part, as communication between the two is not sufficiently frequent for this, so that passengers with limited time at their disposal must make choice before starting.

The Operating Theatres.

NORTH-WEST LONDON HOSPITAL.

Operation for Complete Paraplegia of Four and a-Half Years' Standing; Abscess Opened in Posterior Mediastinum.—Mr. **Mayo Collier** operated on a child, æt. 6, the subject of tuberculous disease of spine in the dorsal region, associated with complete paraplegia of legs and loss of control of rectum and bladder. An incision was made from the spine of the most prominent vertebra outwards to the corresponding rib and transverse process down to the bones. The transverse process was bared and exposed and subsequently removed with an elevator. A careful introduction of a blunt director forwards and inwards was rewarded by the immediate appearance of thick caseous pus. This was removed as far as possible by the gentle introduction of a curette, and subsequent streams of water. A drainage-tube was inserted and the wound closed. Mr. Collier said the operation was extremely easy, the caseous pus appearing immediately on removal of the transverse process. Until quite recently, he pointed out, these cases were allowed to die without any attempt at relief. It was now a matter of extreme satisfaction that the pioneers in surgery of the nervous system had directed their attention to the relief of these cases by opening the spinal canal by the operation of laminectomy. By this procedure many cases were relieved or much improved. A still further advance in the treatment of these cases had taken place, notably in the hands of Mr. Jackson Clarke and others by the operation known as costo-transversectomy Mr. Collier had recently had the privilege of assisting Mr. Jackson Clarke in one of these cases, with the splendid result that a paralysed, bedridden, dying child had been restored to health, and was now walking about with comparative ease and comfort. The present case was a similar one, and Mr. Collier had every right to hope that a similar result might be attained in this case also. It was more or less a frequent procedure to treat psoas abscesses by opening them in the lumbar region close to the transverse processes, but this method of treatment had not been applied to abscesses in connection with disease of the dorsal vertebræ. The abscesses formed and extended in the posterior mediastinum, in close relation to the heart and great vessels, which passed down in front of the spine. These relations had naturally deterred surgeons from active interference.

Operation for Goitre.—The same surgeon operated on a case in which in an exophthalmic goître was pressing on the trachea and causing symptoms of difficulty of breathing and pain in swallowing. The subject was a woman, æt. 25, and the disease had lasted some eight or ten years. The isthmus of the thyroid was much enlarged and protruded forwards. Mr. Collier made an incision in the mid line of the neck, and after exposing the isthmus of the thyroid passed an aneurysm needle, armed with a stout ligature, under the growth on each side of the central enlargement. The central mass being thus isolated was removed and the wound closed. Mr. Collier said that operative interference in many of these cases did not benefit the patient, in others collapse and death was the result, but in those cases where pressure symptoms existed the operation was imperative and should be undertaken without delay. Mr. Collier did not anticipate in this case any but beneficial results.

RICHMOND HOSPITAL, DUBLIN.

Two Operations on the Prostate.—Sir **William Thomson** operated upon a man, æt. 62, who had suffered from prostatic obstruction for two years. There had been great irritation, the patient being obliged to pass water every half-hour during the day and about eight times at night. The prostate felt through the rectum, was enlarged, particularly on the left side. The usual suprapubic incision was made, and the bladder explored. The left lobe of the prostate was enucleated with the right forefinger, but the adhesions were very tough and resisting. The right lobe was quite small, and was allowed to remain. There was no middle lobe.

The patient made an excellent recovery, and is able to retain water for four or five hours, and to pass it in a full stream.

The same surgeon operated on a man, æt. 63, who had come from the West of Ireland, and had been admitted suffering from retention of urine. He had been using a catheter for a couple of years, but a sudden attack of retention could not be relieved, and he was sent to Dublin. On admission a catheter had been passed, and an attack of cystitis allayed after two weeks. The prostate felt like a large pear through the rectal wall. The bladder was incised suprapubically, and the whole of the prostate removed in one mass, this part of the operation taking only ten minutes. The prostatic urethra was removed also. There was a good deal of bleeding, which was checked by hot injections. Subsequently it recurred twice, and it was found necessary to place a plug in the bladder over the prostatic area. Pressure was exerted by traction on a piece of silk carried out through the urethra, and the hæmorrhage ceased.

Sir William Thomson pointed out that Mr. Freyer had published several cases in which the prostatic urethra had been torn away without any untoward effects.

The plug was removed in thirty hours. The patient progressed without a bad symptom. The prostate weighed 900 grains.

The death is announced of Mr. F. Manley Sims F.R.C.S., a well-known practitioner of Mayfair. Mr. Sims had been suffering from symptoms of cardiac trouble for some time, and on Monday, December 9th, he succumbed at very short notice to a recurrence of the attacks. Mr. Sims was 65 years age.

Registered for Transmission Abroad.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

For One Insertion:—Whole Page, £5 0s. 0d.; Half Page £2 10s. 0d.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistancies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion. 6d. per line beyond.

WEDNESDAY, DECEMBER 17, 1902.

THE STANDARDISATION OF DRUGS.

For many years past it has been felt that no sufficient guarantee of uniformity of physiological action of medicinal preparations is afforded by mere directions for the processes of manufacture. It is obvious that unless we can make sure of obtaining identical crude materials—an impossible feat—identity of manufacture will not prevent variations of activity within very wide limits. The subject has been thoroughly threshed out before the Pharmaceutical Society by Mr. Umney, who has formulated certain practical suggestions, having for object to obtain that uniformity of composition and therapeutical activity which is indispensable to the scientific and successful treatment of disease. It is evident that this object can only be attained by ensuring in the galenical preparations a constant proportion of the active constituent or constituents of the drug, and all future methods of standardisation must be based more or less on this principle. This has already been done by several manufacturing firms with a success which doubtless accounts for the preference often shown for their products over those which are merely made in accordance with pharmacopœial directions. Unquestionably this system of standardisation represents a distinct advantage on the old methods; but, as Dr. Attfield points out, the presence of a certain proportion of "total alkaloids" is not in itself sufficient to determine the activity of a given preparation, since this total may represent a mixture, in irregular proportions, of unequally active alkaloids. Many drugs, such as hyoscyamus, nux vomica, ipecacuanha, &c., contain alkaloids, the action whereof is subsidiary, or even antagonistic, to that of the really active principle, and a further desideratum may be deduced from this fact, *viz.*, that galenical preparations should be standardised whenever practicable by a single active constituent rather than by a group of constituents such as would be represented by the total alkaloids. In practice the tendency appears to be towards employing these specially active principles in preference to the original substances with their admixture of inert and possibly antagonistic constituents. The process of standardisation by this method, it is hardly necessary to point out, can only be commercially applicable to large quantities, the cost being prohibitive when only small quantities are titrated. The question arises whether pharmacists would incur any responsibility in selling an article named in the "British Pharmacopœia," prepared otherwise than in accordance with the official directions, but that is a point which we must leave to our pharmaceutical brethren to decide for themselves. When pharmacists have worked out the various problems involved in this improved method of standardisation, their results will, no doubt, be embodied in the pharmacopœia and it will then be possible to enforce a higher, more uniform, and more trustworthy quality of medicinal preparations. At present the limits of variation are too wide, and there is, of course, the danger that pharmacists are tempted to approximate what may be termed the penal standard. The standardisation of medicinal agents drawn from the mineral world is mainly a question of purity, and this is provided for by analysis. It is a satisfactory feature that the question should have been raised by those to whom is entrusted the task of providing medical men with their means of action, and they are unquestionably better fitted to solve the problem than is the practitioner, who is unable to determine in a given case whether the inactivity of a preparation is due to its inherent defect or to the irresponsiveness of the patient.

THE BECK AND CALL OF GENERAL PRACTICE.

There is a widespread belief among the general public that a medical man is obliged, by virtue of his office, to obey the beck and call of any who choose to summon him. The absolute fallacy of that position need not be insisted upon in the columns of a medical journal. There is no legal obligation whatever upon a practitioner to go to persons whom he may not wish to attend, nor need he give any reason for his refusal. The only ground upon which any pretext of compulsion could be based would be a moral one, and we are glad to think that humanity of that kind, in its highest practical phases, is not lacking among the medical profession of the United Kingdom. At the same time, there is a limit to human capability, and in busy practice it is often necessary for the overworked practitioner to husband his energies for the service of his regular patients, even to the extent of declining to attend emergency calls from persons outside that circle in his own district. A recent case at Devonport illustrates the difficulties of the position in a remarkable and instructive way. A boilermaker's wife engaged an uncertificated midwife sixty-five years of age to attend her in confinement. She had previously borne thirteen children, of whom seven were living, and on no occasion had a medical man been present at the lying-in. Her husband was a member of a medical society, but she herself was not entitled to the attendance of its medical officer. Shortly after the birth of her infant, at four o'clock in the morning, the midwife informed her husband that something had gone wrong, whereupon he went off to fetch a district nurse. Failing to find the latter, the husband called up one of two medical men in the neighbourhood, who agreed to come if he was paid his fee of one guinea. Instead of procuring the money or promising to pay the fee the husband went off to the second resident medical man, who, however, failed to attend for some reason that is not made clear in the newspaper report. The husband finally secured the attendance of a medical man from a distance. Upon the arrival of the last-mentioned upon the scene, according to the evidence, he found a condition of *post partum* hæmorrhage and retained placenta, complications from which the unfortunate woman rapidly sank. The coroner took a sensible view of the occurrence, and dissuaded the jury from passing a vote of censure upon one of the medical men. Married men, as he very properly pointed out, had their responsibilities, and they should see that a medical man was engaged to attend their wives in so critical a period as that of childbirth. It would be the gain of the public were all coroners equally sensible and outspoken in their opinions as Mr. J. A. Pearce when he said that, "If people would insist upon engaging those old women, who were nothing more than Sarah Gamps of olden days, then they took the responsibility upon themselves, and must not complain of doctors not attending when the fee was not forthcoming." We may go much further than that, and remark that even with certificated midwives many cases must arise that need the intervention of a medical man. Parliament has seen fit to place a large section of the midwifery practice in the hands of women who, by the nature of things, cannot be equal to all emergencies. They have freely accused the medical profession of sordid motives in opposing the recognition of that hybrid class of unqualified practitioner, yet at the same time they have retained sufficient belief in the good nature and humanity of the profession to assume that its members will be at the beck and call of the midwife to help her clients in emergency. The sentimentalists who have pushed the Midwives Bill through Parliament in the face of the almost universal opposition of general practitioners may now form some surmise of what is likely to happen in the future. Can they be surprised if the medical man refuses to be called up from his hard-earned rest to attend a person who has already engaged services other than professional? A medical man may be up three nights out of the seven with his own patients; why should he be disturbed on a fourth night to go to strangers who are not likely even to pay his fees? That argument is based simply upon the commercial aspect, with which the profession was freely taunted in Parliament. In the Devonport case the husband subscribed to a club; why did he not summon the club doctor? Moreover, there is a parish doctor in every district, whose attendance would be a matter of duty. Why did he not go to the parish medical officer? Why should he choose two busy private practitioners in the district, and decline to pay or to promise to pay their fees? Even in the first instance he turned for help to a district nurse, and only after failing to find her, did he think of going to a qualified man. Can it we wondered if public slander and ingratitude ultimately awaken a spirit of common-sense prudence on the part of medical men in responding to the beck and call of all and sundry in their immediate neighbourhood who may be desirous of securing gratuitous help?

QUACKERY AND THE "RELIGIOUS" PRESS.

We have on several occasions been compelled to refer to the serious action taken by certain so-called religious journals in aiding and abetting some of the grossest and most immoral forms of quackery and charlatanism. A flagrant example has recently been brought to our notice, and after serious consideration, we are of opinion that it is our duty in the interests of the public good, to refer directly to the periodical which has knowingly become the vehicle for the propagation of what we venture to think is one of the worst forms of dishonesty. The winter number of the *Methodist Recorder* has two full-page advertisements, the character of which will be sufficiently indicated by brief extracts. The one emanates from an "oculist and aurist," who declares that "it would appear to be *not known* well enough among suffers from diseases of the eye and ear that a system of treatment exists whereby at their own fireside they may be cured." As a heading there is the sensational announcement, "Valuable Scientific Discovery. Deafness. Blindness. A new method of treatment without operation. The Blind See. The Deaf Hear." The greater part of the page is filled with "testimonials." Another page of this "religious" periodical is devoted to an "institute of chest specialists." In large and arresting type we read: "Hope for the 'Hopeless!' Consumption, asthma, bronchitis completely and permanently cured." The reader is then informed that "The treatment strikes right at the seat of the disease and entirely eradicates it in a remarkably short time." And the treatment is such that "it can easily be carried out by any sufferer in his or her own home, and need not interfere with the occupation where same is still followed." Needless to say that in both cases the advertisements are so framed as to impose on the ignorant and inexperienced, and clearly indicate the cruel and unscrupulous methods of the advertisers. But it is not our purpose to find fault at the present time with the advertisements themselves, but with the conduct of those responsible for the publication of this so-called "religious" paper.

This paper, in regard to the publication of risky advertisements, is an old sinner, and still, unrepentant, carries on its deeds of darkness. We are informed that numerous efforts have been made to prevent the appearance of objectionable advertisements. The attention of the Editor has been frequently drawn to the evil resulting from their appearance. The authorities of the church of which the Editor is a "minister" have been approached by medical men of the highest position in the profession, but nought avails to arrest the scandal. We understand the paper has a very large circulation among the worthy working class, and gains entry into many a village home. Under the guise of religion, physical and financial loss is being wrought throughout the country, and needless suffering and oftentimes death is the result. It may seem unreasonable to attempt to rectify the errors of "the children of light," but we count it an absolute duty to warn practitioners working among our "believing" operatives, and medical men practising in country districts, of the subtle danger which is gaining entrance into many a home through the pages of this attractive magazine; and we hope our energetically ethical contemporary, *Truth*, will see its way to assist the profession in warning intelligent "Methodist" laymen throughout the country of the pernicious influence, which, like the devil in monk's garb, seeks to clothe deceit in the cloak of religion.

Notes on Current Topics.

Lord Lister's Jubilee.

Fifty years have gone by since Mr. Joseph Lister, now Lord Lister, was admitted a member of the medical profession, a date fraught with an importance to medicine and to humanity little suspected at the time, but one which will be remembered throughout the ages. His teaching has left an impress on medicine as obvious and as indelible as that of a Galileo or a Darwin in this respective domain, it forms an integral and indissoluble part of the scientific acquirements of the world at large, and it influences the conduct of practitioners wherever medicine is practised. It would be a gigantic error to suppose that the principles of antisepsis apply only to surgery. Their influence has been exerted in practically every department of the healing art, and it is indeed the most remarkable, and perhaps the most successful, of the achievements of preventive medicine. Placed side by side with the progress which Listerian principles have accomplished, those of the most gifted physician, the most brilliant surgeon, pale their ineffectual fires, for the one is peculiar to the individual, the other is the common property of humanity. Rarely has it been permitted to man to witness the universal adoption of principles in their inception so diametrically opposed to the ideas then prevalent. His principles prevailed in virtue of their essential truth, not forced upon a reluctant world by the dialectic sword or propagated by the tireless pertinacity which confers notoriety, if not fame, upon discoveries of comparatively trivial importance. Lord Lister, with modesty and simplicity, gave his results to the world, and little by little they banished the horrors of the operating theatre from our midst. It must be a source of intense satisfaction to all who have the interests of suffering humanity at heart to reflect that Lord Lister is still among us, full of years and honours, to enjoy the spectacle of a rejuvenated art, and to receive the congratulations of an admiring and grateful professsoin—a profession which is not limited to any one nationality, but carries on its beneficent work throughout the world. The fame which is Lord Lister's is one which the greatest may well envy. It surpasses that of Jenner in that it reposes on a much wider base—it is, in truth, the reward of the discovery of a system, and not of an isolated fact.

An Unusual Abdominal Tumour.

Considering that the abdominal walls are soft and yielding throughout their whole extent, it might reasonably be expected that tumours in the cavity should be readily diagnosed. But, as Sir Thomas Watson long since pointed out, the contrary is the fact. A tumour occupying the mesial line of the abdomen that in February last came under the notice of Dr. Franceses Villa, of Milan, was a good example of the difficulty of diagnosis in such cases, and is also worthy of record as one of the few cases of solid pedunculated tumours of the urachus that have been discovered. The patient, a woman, forty-five years old, came complaining of a severe pain at the site of her navel which had continued almost without intermission for three months. The pain extended transversely across the abdomen, and was attended by some constipation. The recti muscles were hard and rigid, and so much contracted that the patient was forced to assume a stooping attitude. Deep respiration did not intensify the pain. Her viscera were healthy, her urine normal in amount and frequency. Early in the disease carcinoma with occlusion or narrowing of the transverse colon was diagnosed. On opening the abdomen Dr. Villa found a pedunculated solid tumour attached to the posterior wall of the umbilicus, to the posterior surface of the right rectus muscle, and so intimately attached to the apex of the bladder as to necessitate the excision of a considerable portion of the wall of the viscus. The tumour, which was vascular, was the size of a large goose egg, and to its posterior surface some loops of small intestine were adherent. One of the principal difficulties in the diagnoses of abdominal lesions is our lack of knowledge of the physiology of the sympathetic nerve. When we know the part it plays as a sensory and trophic nerve we shall be the better able to judge of the symptoms associated with the presence of abdominal tumours.

Lime Salts in Epilepsy.

A series of very interesting experiments on epileptic patients, varying from fourteen years to thirty-seven years of age, has been conducted by Signors Hudenino and Borelli in the clinic of Lombroso. Noticing in many epileptics that lime salts were badly and sparingly assimilated, they decided to try the effects of lime salts on well-marked cases of the disease. They commenced by giving lime water, and finally prescribed the bromide, the lacto-phosphate, and the carbonate. They believe that the lime salts lessened the severity of the attacks and lengthened the intervening interval. In one case the time between the seizures was increased by forty days, and in another by one hundred and fifty-six days. Recognising that lime is absorbed in very small quantities from the alimentary canal, the authorities decided to try the effect of lime administered hypodermically. Of four cases so treated one recovered, but the three others showed no sign of improvement. Without claiming any curative properties for the lime salts in the treatment of epilepsy, the authors say that lime given hypodermically, or by the mouth, has the power of diminishing the number of the attacks and lessening their severity, and with Sabbatini they believe that lime salts have a quieting influence on the cerebro-spinal nervous system.

Laboratories in Wards.

There is perhaps at the present day a tendency, principally in the richer schools of medicine, to exaggerate somewhat the position of the clinical laboratory in the training of the student. He is taught sometimes—not, indeed, to place too much reliance on bacteriological and pathological results, for that is impossible, but to place too little confidence in the results of careful clinical examination of his patient, or to shirk the bedside investigation for the more mechanical methods of the laboratory. It must not be forgotten that phthisis was diagnosed accurately before Koch, diphtheria before Klebs and Löffler, and typhoid before Widal, and though the methods associated with these names are of inestimable value as an aid to diagnosis, yet the student should not rely entirely on them, but should be trained to form a careful opinion at the bedside, correcting it by his laboratory results. Yet true as this is, we cannot go quite as far as some distinguished clinical physicians and others in their reaction against the domination of the laboratory. For instance, Dr. Shepherd, Professor of Anatomy at McGill University, in his presidential address to the Canadian Medical Association, urges the relegation of laboratory training to the first two years of the medical course. He proceeds:—"Such giants as Pasteur, Lister, Koch, and others were not produced by magnificent laboratories . . . they made their opportunities and forced Nature." Very true, but before the days of magnificent laboratories the work of such giants was impossible, and if there were anything beyond rhetoric in Dr. Shepherd's argument it would hold equally against universities and colleges, and even his own dissecting rooms.

Medical Students.

The modern medical student has become a very different kind of man (and woman) from the type made famous by the literary labours of Albert Smith a couple of generations ago. The ever-increasing stringency of high standard examinations renders the life of the aspirant to medical qualification both anxious and laborious. To-day there is no leisure for cider-cellars and "half-and-half" and the boisterous rowdiness pictured by the classical historian of student life in the days of our grandfathers. After all, the change is perhaps not so much greater in this particular class than it has been among society in general. The tradition of the rowdy medical student, however, still lingers in the popular mind, where the belief is most likely fostered by the newspaper reports of police cases in which medical students are said to be concerned. The fact is, of course, that any person in a scrape finds it easy and convenient to describe his occupation in that way. In this way the name of an honourable and steady-going class of society is daily dragged in the mire. An effectual remedy, strange to say, is ready at hand in the shape of the Medical Students' *Register*, published yearly by the General Medical Council. A copy of that work ought to be at every police court as well as in the possession of every newspaper editor. A glance at its pages would settle off-hand the right of any prisoner or defendant to describe himself by the appellation of "Medical Student."

' Over-Nutrition" *versus* Degeneration.

The frequent failure of medical education to educate the higher mental faculties is now and then illustrated in a striking fashion in the various courts of law. In giving evidence a scientific witness is often required to justify his opinions and compelled to refer facts to their causes. Unfortunately, the whole scheme of modern high standard medical education appears to aim at the acquisition of huge masses of particular phenomena and observations, to the crowding out of general laws and principles. The result is a qualified man somewhat in the position of a mariner who steers by the stars, but whose knowledge of navigation would not permit him to navigate through a spell of fog and darkness. In other words he is purely empirical. An instance of outer professional ignorance of the sort we have in mind was afforded not long ago at an inquest, where a medical man testified as to the results of a post-mortem examination. Deceased, he said, died of exposure and cardiac failure. The latter was due to fatty heart, and the liver and other organs of the body were also in an advanced stage of fatty change; indeed, they were in a "hopeless state of over-nutrition" from the effects of chronic alcoholism. This farrago of nonsense evidently arose from a confusion of what may be called healthy or storage fat and that resulting from tissue degeneration. The incident throws a side-light upon medical education that will give pause to the authorities responsible for our modern curriculum and its educational tests.

Operation for Ruptured Intestine.

The report of the Boston City Hospital for 1902 contains several cases of successful operation undertaken for rupture of intestine, and this may serve to encourage surgeons to resort to operative measures whenever there is reasonable cause to suspect the occurrence of this grave lesion. As a matter of fact, surgeons hardly need encouragement in this direction, since no one would hesitate to intervene were he certain that laceration or perforation had actually taken place. In view of the fact that this injury may occur without any outward or visible indication of the gravity of the accident, the question turns rather upon the conditions under which the surgeon is justified in operating. Obviously, if he only operates in cases which do not admit of any doubt, he will sacrifice a certain proportion of patients, because the question of time here, as in so many other abdominal conditions, is all important. Every hour of delay adds materially to the danger, and unless the operation be undertaken within a few hours of the accident the risk of a fatal issue becomes progressively greater. We cannot wait for signs which will make the diagnosis absolutely certain, for by so doing the value of the intervention will be jeopardised, and as operation holds out practically the only chance of recovery, and as, in many instances, its existence can only be made out by operation, the sooner this is done in suspicious cases the better for the victims of this kind of traumatism as a class.

The Gordon Memorial College at Khartoum.

Dr. Andrew Balfour, of Edinburgh, who has been appointed director of the bacteriological laboratories of the Memorial College at Khartoum had a hearty "send-off" a few days since at a dinner provided by Mr. H. Wellcome, at the Prince's Restaurant, when many eminent scientific and medical men were present in honour of the occasion. The laboratories in question have been presented to the government of the Soudan by Mr. Wellcome, whose munificence took this form consequent upon his travels in this interesting region, many trophies from which graced the dining-room and the adjoining hall. The laboratories have been specially fitted to enable the study of tropical diseases to be carried on *sur place*, and provision has also been made for medico-legal investigations, water analysis and researches in the department of agricultural and mineral chemistry. The gift, it will be seen, is one of incomparable value and importance, and may be trusted to yield encouraging results. The toast, "Success to the College," was proposed by Sir H. M. Stanley, who described in eloquent terms the rapid progress that is being made in the civilisation of the Soudan, and held out hopes of a great future for the children of the Soudan, "the heirs of the ages.' Mr. Wellcome proposed Dr. Balfour's "health and prosperity," and expressed his conviction that the climate of the Soudan would be found excellent in the treatment of tuberculosis. Mr. James Cantlie, Sir Dyce Duckworth, Sir Richard Douglas Powell Bart., and others also spoke on tropical medicine, and clinical and bacteriological research. Dr. Balfour carries with him our best wishes for the success of his career in the Soudan, where subjects of research in abundance await him.

Gonorrhœal Endocarditis.

Among the most dangerous, but luckily least common, complications of gonorrhœa is endocarditis. When it does occur it is, of course, the result of a general blood infection of a septicæmic nature, and in nearly every case the specific organism has been separated from the blood in circulation. Drs. Harris and Johnston, of Johns Hopkins, have recently (*Johns Hopkins Hospital Bulletin*, October, 1902) placed a case on record, and have given a careful analysis of the other recorded cases where bacteriological examinations had been made. During life the authors separated the gonococcus from the blood, while after death it was cultivated both from the heart's blood and from agitations on the mitral valve. In cultivating the organism from living blood, the latter should be but slightly diluted, and it is advisable to mix it with melted agar and then plate, rather than to attempt a liquid culture. The bacteria become more plentiful as the disease progresses, and the blood does not seem to gain any bactericidal power.

Medical Men and Deaths under Chloroform.

At an inquest held at Bournemouth last week on the body of a man who had succumbed while under the influence of an anæsthetic, administered for the purpose of performing an operation for the relief of appendicitis, some remarkable circumstances came to light which appear to call for comment. The patient had been under treatment for chronic appendicitis with pleurisy, and a subdiaphragmatic abscess being suspected, attempts were made to reach it, but had to be relinquished on account of the hæmorrhage. A subsequent attempt proved equally futile. Ten days later it was decided to remove the appendix, and A.C.E. mixture was given with that object in view. When, however, the patient was placed on the operating table he collapsed and died. Some hesitation was experienced in giving the certificate of death—as well there might be—and ultimately information reached the authorities which led to an inquest being held. The post-mortem examination made by the police surgeon showed that the body had already been examined after death, and the witness stated that in his opinion the man was not in a fit state to undergo anæsthesia, being, in fact, in an advanced stage of septicæmia. Dr. F. T. Gardner, who was in charge of the case, was sharply reprimanded by the Coroner for having omitted to refer the case to him forthwith. He defended his hesitation in regard to the certificate on the ground that coroners did not invariably insist upon holding an inquest under such circumstances, but he was unable to mention a specific instance in which no inquest had been held. His conduct in making a post-mortem examination on his own account without mentioning this in his evidence was also strongly condemned by the coroner. It is hardly necessary to point to the undesirability of departing from the usual course in such a case. Obviously everything was done that could be done for the unfortunate patient, but surely every medical man is aware that death under an anæsthetic is a proper subject for inquiry and, this being so, that a private examination of the body is highly improper. The Coroner disclaimed any intention of criticising the propriety of administering chloroform in this particular case, nor, indeed, could he well have done otherwise, seeing that the three medical men present approved of its use. The case is one which should serve as a warning to medical men always to court publicity after an accident of this kind, if only for the purpose of exonerating their own responsibility.

Orchitis from Strain.

The occurrence of orchitis apart from urethral infection has been called in question, but judging from cases recently reported to the French Chirurgical Society such may be the case, and the point is of some interest in view of possible medico-legal and social complications. Non-infective orchitis of this kind is characterised by a tendency to recur under similar circumstances, by its moderate intensity and by the promptness with which it undergoes resolution. This form of orchitis is *a priori* more likely to present itself in persons who have previously suffered from some other form of testicular inflammation, but in such subjects it is, of course, impossible to ascertain what precise share strain *per se* takes in its production. The essential point to bear in mind is that orchitis is not necessarily due to urethral infection or direct external traumatism.

The Drouet Institute for Deafness.

Of all the heartless "cures" that can be palmed off on a credulous public, that which professes to remedy deafness is one of the most pernicious. In spite of frequent exposure in our own columns, as well as those of other journals, however, the notorious Drouet Institute continues its career, apparently with unabated success. Our fearless contemporary, *Truth*, has been untiring in his endeavours to scotch this insidious enemy of the community. In his issue of December 11th, the Editor, commenting upon the advertisement of the Institute in *Household Words*, remarks that "when the same swindle is freely advertised by the wealthiest and most influential of London papers, perhaps one is not justified in throwing stones at Dickens' old journal." That observation reminds us that the *Daily News*, in common, it is fair to add, with other metropolitan dailies, inserts Drouet's advertisements. Now, the *Daily News* excludes betting news on grounds that are irreproachably moral and didactic. It seems hardly consistent, however, for the same journal to be receiving large sums of money for the advertisement of what has been again and again publicly denounced as a shameless imposture. A few days since a church dignitary was heard in a public vehicle advising an anxious mother to take her son to the Drouet Institute. In answer to a suggestion of unqualified practice, the reverend gentleman said it had been found absolutely impossible to prosecute Drouet. That hardly represents the right view of the case, as Drouet has never brought an action in self-defence, although urged to publicly again and again by all kinds of injurious and opprobrious epithets.

Laparotomy in Typhoid Perforation.

Surgical intervention for the relief of perforation of a typhoid ulcer has not hitherto been attended by any great measure of success even in hospital practice, where alone the intervention is likely to be resorted to without dangerous delay. One cause of the failure to save life is apparently that although only one ulcer may actually have perforated others are on the point of giving way and ultimately do rupture, thus vitiating the result of the operation. From the medical point of view the great obstacle lies in the extreme difficulty of deciding whether or not perforation has actually taken place. The absence of liver dulness which is such a valuable guide in perforation of a gastric ulcer, for instance, is of less significance in these cases because the marked abdominal distension usually associated with an attack of typhoid fever may mask it even in the absence of actual perforation. The trend of opinion seems to be that when there exists a reasonable probability of an ulcer having given way it is well to operate, especially as perforation in typhoid fever usually takes place late in the course of the disease, that is to say, after the third week, at a time when the patient is in a state to withstand the operative shock. It is generally agreed that operative measures for perforation which supervenes during the active, acute stage is useless, and, if resorted to, is likely to bring the procedure into unmerited discredit. Physicians no longer evince any reluctance to requisition the services of the surgeon in these cases, since, although the chances of recovery are small, they are desirous of affording their patients this one desperate hope of being spared the otherwise unavoidably fatal issue. It is possible, however, that small perforations take place more frequently than one is apt to suppose, in the absence of the characteristic symptoms, and there is actual evidence that such perforations may and do undergo spontaneous healing. The supervention of the classical symptoms of perforation—a brusque fall of temperature with acute abdominal pain, sweats and profound collapse—probably indicate not only that perforation has occurred, but also that the perforation is one of some magnitude.

On Christmas Fare.

CARELESS of the origin of Christmas rites, the average Briton turns with stolid contentment to their celebration by the generous aid of kitchen and cellar. This indulgence applies happily more or less to all ranks and conditions of men among us, for at this time of the year the rich are not forgetful of the wants of the poor, for whom plum pudding and beef, not to mention ale and tobacco, are provided wholesale in all parts of the kingdom. The solid, strong and sober taste of our countrymen, we are proud to think, has solved the question of what is best to eat at Christmastide in a fashion that is final, for it is useless to gild refined gold. We have set our solemn seal of approval as a nation, upon such triumphs, natural and artificial, as turkey, goose sirloin of beef, plum pudding, mince pie, the which we garnish for the feast with mistletoe and holly, and wash down with nutbrown ale, sound claret or port, and a glass of punch withal. Yet this array of fare, though toothsome and even rich, hath no grain of malice, for he who eats of it without excess to-day may indulge again to-morrow. We are proud to think that nowhere outside the United Kingdom can plum puddings be properly made. There is some charm, seemingly, in our capricious atmosphere that is essential to the birth of that king of dishes, witness the fact that thousands of tons of plum pudding are sent forth yearly to every corner of the inhabited globe. It is not a little consoling to be able once and for all to dissipate the musty popular joke which attributes all kinds of maladies to Christmas fare, earmarking that wintry holiday as a very windfall for medical men. On the contrary, a merry Christmas is the best of all pick-me-ups for jaded mankind.

Diphtheria in Carlisle.

OWING to the prevalence of diphtheria in Carlisle the attention of the local authority has been called to the matter by the Local Government Board. The Medical Officer of Health was thereupon directed to furnish a special report upon the subject. His subsequent communication to the Health Committee appears to have dealt chiefly with a certain school to which a number of cases of the malady in question had been traced, and which had been closed three weeks before. Overcrowding, according to the report, has been allowed to exist to a scandalous extent, mainly owing to the slipshod custom of admitting school children who were not on the register. In the main room of the infants' department the figures given allowed about three feet of floor space to each child. The walls and school furniture and equipment were in a filthy condition, and much of the material was destroyed by the Sanitary Inspector. The teachers had suffered from sore throats and headaches for some time past, and one had contracted diphtheria. After an exposure of this kind one would like to know something more about the system under which such a state of affairs could have existed. Why has not the condition of the school been brought long ago under the notice of the local sanitary authority? A matter of this kind is of interest wherever there are schools and school children. Perhaps some of our Carlisle readers will kindly supplement and extend our information as to the particular school that figures with so little credit in the official report.

Lunatic Asylums in Venice.

THE correspondent of a usually well-informed London newspaper has forwarded a description of the terrible treatment to which lunatics are subjected in Venetian madhouses. These revelations are the outcome of the labours of an official commission of inquiry appointed by the Prefect of Venice. Want of ventilation, filth, overcrowding, and other hygienic defects form a small part of the indictment. Medical inspection appears to have been irregular and perfunctory, and often absent for days together. Violent patients were bound in their beds by leather bands tightly drawn about the throat, wrists, and ankles. In one cell, too small for the accommodation of a single inmate, two women were found. One of them was very ill, and lay free on her bed. The other wore round her waist a heavy leather girdle, to which her hands were fixed, and in that condition she was chained to a ring in the wall. Similar rings were found in all the cells. It is gratifying to learn that the Prefect of Venice has suspended the governors of the asylums incriminated, and it is to be hoped that henceforth modern humane methods will be introduced into Venetian asylums. It seems incredible that such a state of affairs could exist nowadays. For all that we should remember that it is not so many years ago since equally barbarous methods prevailed in our own country with regard to asylum treatment. Happily, the old idea that insanity was caused by the invasion of devils, who could be cast out only by harsh measures, has become a thing of the past in all civilised communities.

Destructor Refuse.

THE burning of town refuse in a "destructor" is regarded by most persons as a drastic method of "purification" by fire of a heterogeneous mass of undesirable material. No one who has seen the workings of that fiery holocaust could imagine the issue therefrom of any germ of life. The local authorities of Yarmouth, however, appear to doubt the efficacy as a germicide of the destructor which disposes of the refuse in their ancient town. The question arose out of a report submitted by their medical officer of health, calling attention to the prevalence of diphtheria, and suggesting a number of precautions to be taken with a view of keeping the disease under control. Thereupon a Councillor solemnly advanced his private theory that one cause of diphtheria among young children was the refuse from the destructor used on the roadways. He further stated that in some parts of the town the nuisance caused by the material mentioned was simply unendurable. If that be the case the destructor used by the Yarmouth Town Council must be of a kind fortunately unknown to the majority of mankind. An efficient apparatus will burn ashpit and road refuse, to say nothing of sewage, and leave behind practically inodourless ashes and clinkers, in which no germ of diphtheria or of any other living thing could possibly exist at the time of leaving the furnace. During the process of burning it is true that the most abominable odour often poisons the whole neighbourhood, but that is a thing apart from the solid refuse of combustion. It would be more to the purpose were the Yarmouth councillors to look after the salt water flushing of alleys, the supply of anti-diphtheritic serum, and the other excellent measures advocated by their medical officer.

The Illness of Lady Dudley.

We are glad to be able to inform our readers that her Excellency the Countess of Dudley continues to make steady progress towards recovery. As is well-known, Her Excellency developed a severe attack of acute appendicitis which necessitated an operation on December 8th. The operation was performed by Mr. C. B. Ball, Regius Professor of Surgery in the University of Dublin. The bulletins which have been issued twice daily have on almost every occasion born testimony to steady improvement, and we may expect that in a few days her Excellency's medical advisers will be able to pronounce her to be out of danger.

Ginseng, a Chinese Aphrodisiac.

As an article of commerce the root of the *Arabia quinquefolia* has a considerable and increasing value in North America. It is greatly prized by the Chinese for its medicinal uses, the nature of which is not exactly known, but which is generally supposed to be of an aphrodisiac character. The American plant is closely allied with the *panax* or *Arabia ginscheng* of Eastern Asia. Its roots were formerly collected in the woods in North America, where they were indigenous, but they are now cultivated in that country on a somewhat extensive scale. As the roots can be sold in the States at two dollars a pound; while in China the best quality commands as much as sixteen dollars a pound, the cultivation of the plant clearly opens up a wide field of commercial promise. It is interesting to recall the fact that this curious root figured largely in the time of the South Sea bubble at the beginning of the 18th century. During that period of speculative mania ginseng root sometimes changed hands at the exorbitant price of sixty guineas a pound. At its present modest market value, home cultivation would well repay the Chinese farmer, and it may be supposed that before many years have elapsed, that fact will be appreciated by the wily natives of the Flowery Land. The medicinal virtues of ginseng have not commended themselves to the Western scientific mind, although it is possible that the root may contain properties worthy of further investigation by experts in materia medica.

Bishops and Babies.

That British bishops are not all bachelors and celibates is generally known, but it has been left to Mr. H. G. Wells to discover that the birth-rate in episcopal families is conspicuously higher now than it was a hundred years ago. The family circumstances of the bishops and archbishops between the years 1770 and 1800, and between 1870 and 1900 have been investigated. In the former period there were 45, of whom 38 were married, with a total of 150 children, giving an average family of 3·94; while in the latter period of 52 ecclesiastics, 44 were married, and the total number of children was 241, an average family of 5·47. These surprising figures would furnish a text for a lay sermon and certainly offer material for interesting speculation. With a falling birth-rate in the country it is astonishing to find the episcopacy offering such a practical protest. Does it mean that this particularly select body of mankind is becoming our proletariat and so compensating for the less prolific of the community? We hope this new and ingenious form of research will lead to further revelations. Such figures tend to lighten the monotony of vital statistics.

The Hygiene of the Scottish Tinker.

It is a remarkable fact that, in spite of all progress in sanitary matters there are certain sections of the community which remain to a certain extent outside the sphere of action of hygienic reform and sanitary law. The vagrant and vagabond classes, the professional tramp, and the gipsy all continue in open opposition to procedures essential to health and neglectful of moral obligations. But among the migratory "unfit" the Scottish tinker presents many features of particular interest to the sociologist and sanitarian. Mr. John Macdonald has made this interesting people the subject of careful study, and his paper on "Tinker Children," in the recently-published "Proceedings of the Third International Congress for the Welfare and Protection of Children," is deserving of thorough consideration. The northern Tinkers are found usually north of the Forth and the Clyde. It is estimated that there are about 300 families in the Highlands. Formerly they were hawkers and repairers of tinware, as their name indicates, but since zinc and enamel ware have replaced tin they live almost entirely by begging, which is carried on chiefly by their children. The farmer often finds the tinker a good and cheap labourer, and therefore encourages him in his shiftless habits. In some cases the tinkers have provided themselves with caravans and ply the trade of the hawker. But the greater number live in tents, and some in winter time make a home in caves. They are exposed to much hardship, and in cold weather their lot is deplorable. It is said that half the children die within the first year. The great vice of the tinker is drunkenness. He has no inducement to be provident, and is utterly disregardful of hygienic requirements. The adults are absolutely ignorant, being able neither to read nor to write. The children, generally speaking, receive no education. They just follow their parents, much as a dog does his master, inheriting and copying the vices of their elders and perpetuating what has been the tinker's life for generations, with little change and practically no improvement. In short, the life of a tinker is the life of a savage. Attempts have been made to bring this wanderer within the restrictions and controlling influence of civilisation, but hitherto with but little success. The tinker is a picturesque feature in the Scottish landscape, but he is in many ways a menace to the moral and physical health of the community. As a chain depends for its strength on the stability of the weakest link, so the well-being of a people may be rightly judged by the measures of protection extended to the weakest individual. Estimated by such a standard we have still room for much expansion in the application of hygienic methods to the migratory classes, and especially to the interesting but neglected folk we still pleasingly designate—tinkers.

Literary Atrocities.

The most curious example, which we have ever come across of writing for writing's sake and of a quaint taste for the use of non-existent terms, is to be found in an article in a contemporary entitled "Landmarks in the Uterus." The title does not convey much, if any notion of the subject matter of the article, which consists of a mass of real and assumed facts, either remotely or nearly connected with the uterus, strung together without any apparent motive or object save to enumerate the facts in the longest words possible, and to omit such literary small game as articles and other monosyllables. Most curious are the terms invented for the occasion, and the "results" which are apparently bound up with certain "age periods" in the history of the uterus. The most fascinating of the many extraordinary terms are, perhaps, those used to convey the relations of the uterus to the rest of the body. *Holotoly* implies its relation to the "general body," *Skeletopy* to the osseous skeleton, *syntopy* to the adjacent viscera. *Idiotopy* conveys the relation of component uterine segments to one another. *Pueritas* is the term applied to childhood—a nicely sounding word enough, but some better reason than that is required for its existence, as it is not to be found in any Latin dictionary with which we are familiar. Amongst many other facts we learn that "the tractus urinarius shares in altered vascularity with the tractus glentalis during its crisis or during its maximum functions as pubertas, menstruation, gestation, puerperium, and climacterium. It is most evident in gestation when renal secretion is disturbed, nephritis, albumen, also in the climacterium when renal secretion is excessive, deficient, or disproportionate!" It is unnecessary to add that this extraordinary performance is American in origin; true, it is somewhat of a failure as an attempt to instruct, but as a collection of polysyllabic words of uncertain etymology it is very hard to beat.

The Physiology of Laughter.

There may be some foundation for the view of our Continental neighbours that we are a "sad" people, but we may at least congratulate ourselves that an Englishman has furnished the world with a serious work on Laughter. Professor Sully's new book, "An Essay on Laughter," will not only furnish much material for the psychologist, but cannot fail to interest the physiologist, and we venture to think will prove of no little service to the observant medical practitioner. The evolution of the laugh is certainly worthy of systematic study. If we consider it as an exaggerated and vocal smile, it is necessary to trace its first appearing in the infant and seek its early manifestation in the higher apes. Its physiological mechanism is complex, and it is not easy to make clear discrimination between the laugh and the sob or sigh. Transition from the one to the other is ready and frequent. And one cannot afford to neglect those forms of expression which, in states of mental alienation must be considered as more or less pathological. If it be one of the chief objects of the doctor's service to bring back to his disconsolate and despairing patient the tonic and invigorating influence of "a good laugh" it will be well that he should investigate its origin, nature, and action.

Royal University of Ireland.

His Majesty the King has been pleased to appoint the Right Hon. the Earl of Meath to be Chancellor of the University in succession to the late Lord Dufferin. The Right Hon. the Earl of Westmeath has also been appointed to be a member of the Senate. The Vice-Chancellorship of the University still remains vacant no appointment having been made thereto since the death of Lord Morris and Killanin; it is invested in the Senate and we understand will be filled in the near future. This would have been done in January last but for an irregularity in the election of direct representatives of graduates of the University on the Senate.

PERSONAL.

Mr. L. **Sworn**, of Epsom College, has been elected to a mathematical scholarship at New College, Oxford.

Professor J. Rose Bradford, F.R.S., has resigned the post of Professor-Superintendent of the Brown Animal Sanatory Institution.

Miss Constance A. Bennett, M.B., B.Ch., Dublin has been appointed Resident Medical Officer to the Dundee Poorhouse and Hospital, in succession to Dr Laura Saneman.

Professor Isidore Neumann, of the University of Vienna, having attained the age limit, resigns the chair of dermatology as from the end of the year, and Professor Franz Maracek has been appointed his successor.

Dr. A. Loir, a nephew of the late M. Pasteur, has gone to Buluwayo in order to establish there a branch of the Pasteur Institute for the treatment of rabies. Of late there have been many cases of the disease among domestic animals in Rhodesia.

Dr. Stevenson, M.O.H. for Clydebank, was entertained at a dinner by the inhabitants last week, when a handsome presentation was made expressive of their appreciation of his kindly and efficient services in the district during the last quarter of a century.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

BELFAST.

[FROM OUR OWN CORRESPONDENT.]

Ulster Medical Society.

The opening meeting of the Session was held in the new Medical Institute, Belfast, on Thursday last, December 11th. The President, Dr. John Campbell, occupied the chair, and delivered his inaugural address, taking as his subject, "The Relation of Medical Men to each other and to the Public."

Before entering on his subject the speaker, Dr. Campbell, expressed his pleasure at being the first to occupy the chair in the new institute, the generous gift of his predecessor in the chair, Sir William Whitla. The speaker then proceeded to refer to the relations of medical men with each other. He said that in Belfast the general relations were, on the whole, very good, and quoted the opinion of the late Dr. Lawson Tait to that effect. Many men were ignorant of the fact that ethical rules had been published and endorsed by the profession, which would be found to afford guidance in almost every ethical difficulty, and these should be read by every young medical man before entering on the practice of his profession—for many mistakes were made through ignorance.

Patients changing their medical advisers were fruitful sources of difficulties and misunderstandings, and, unfortunately, the medical men who felt aggrieved blamed, not the patient who was often chiefly to blame, but his supplanter. In these cases a frank and friendly conference between the medical men of the neighbourhood would do more to smooth matters than anything else.

As regards consultants, the ideal consultant would, no doubt, be one who never saw any case except with the general practitioner in charge of it, but this course was impossible to follow, as the custom of seeing all comers at one's own house was firmly established. The consultant had difficulties both with the public and his fellows. A section of the public looked on all medical men as guessers, and went from one to another, hoping eventually to find one who, according to their ideas, guessed right. In dealing with his fellow medicals, the consultant might write to tell them of cases he had seen at his house, but if he did they sometimes resented what they considered his interference, and if he did not they might consider themselves slighted. The sum of the matter was that the consultant must consider the patient first, but carefully avoid anything that looked like an attempt to exalt himself or his own importance at the expense of the general practitioner. The duties of the profession to the public were very varied—we were advisors, confessors, and friends. Perhaps our hardest duty was to fight against a feeling of contempt for foolish people, and avoid cultivating a cynical attitude towards the weakness of humanity. The public generally believe on the possibility of putting a name to every ailment, and in the existence of a cure for each. Though admitting that death must come to all, they seldom admit that it comes at the right time, and believe that if only the doctor had hit on the right treatment its coming might have been delayed.

The large majority of the public were honest and straightforward, but a minority gave trouble; chief among these were the gossip-mongers. Rumour is ever a lying jade, but never more so than when she deals with medical matters.

A lower class of people were those who tried to extort money, sometimes by threats, but these were best dealt with by a medical protection society. Finally, there was the class of people who contract bad debts, going from one doctor to another, and paying none. It was well to be very suspicious of any new patient who began by running down their former medical attendant, and we should inquire whether the latter had been paid. We might find that we in turn should be deserted, and calumniated when we ventured to press for payment.

Referring to hospital abuse, the speaker expressed the opinion that inquiry regarding the patient's circumstances, either by a paid hospital official or by the doctor, was of little use, and the best solution of the question was to make hospitals as much as possible places for consultation, patients bringing letters from their own medical men. As regards clubs and under-paid Poor-law appointments, we have the remedy in our own hands, and can defend ourselves by combination. We have seen the success attending combined efforts to improve the conditions under which our colleagues serve in the Army and Navy. When all is said and done, it must be admitted that most of the disadvantages from which we suffer are our own fault.

Co-ordination, combination, and *esprit de corps*—these are what we want, and to promote these in Ulster Sir Wm. Whitla has done more than any other man, by providing the Ulster Medical Society with a house where the members will meet for professional and social intercourse.

At the conclusion of the address, which was very warmly received, the President invited the members to adjourn to the library for coffee and cigars, and subsequently a large number stayed to enjoy the amenities afforded by the rooms of the Medical Institute; billiards, bridge, and whist forming a pleasant variety from the duties of the day.

Literature.

RAYMOND'S CLINIQUE DES MALADIES. (a)

These two large volumes embody the lectures delivered by Professor Raymond at the Salpetrière, and are filled with facts and observations drawn not only from the stores of an erudition peculiarly rich with the science, ancient and modern, of many countries, but also from the experience of a clinical observer who has had ample opportunities of studying diseases of the nervous system. The subjects dealt with are numerous and diverse. In Chapter VII. he deals at considerable length with the psychic equivalents of epilepsy. Here he remarks that psychologists, by throwing themselves with the greatest enthusiam into the study of hysteria, have almost completely neglected the study of epilepsy, and that in works on epilepsy there is no trace of the innumerable modifications of conscious sensibility, voluntary movement, emotions, attention, and ideation, which are so frequent in their treatment of hysteria. After a minute description of an attack of *grand mal* and *petit mal*, he goes on to state that these attacks may be replaced by symptoms quite different, and gives three varieties:—(1) Motor psychic equivalent, (2) sensory psychic equivalent, (3) purely psychic equivalents, and numerous interesting examples are given to illustrate each of these varieties. These varieties of epileptic delirium, he states, often take a form of mania. They are extremely dangerous, and may result in criminal acts, homicide, incendiarism, theft, and outrage on decency. Another chapter is taken up with an interesting and graphic description of a case of crossed paralysis, and here he states that in the vast majority of cases of crossed paralysis a local lesion of the pons and medulla region is indicated. Chapter IX. is taken up with a description of cases of tumour at the base of the brain; here also the cases are minutely described. In Chapter XXVII. he treats of juvenile general paralysis. Treatment with mercurial inunction and potassium iodide internally he found to produce a certain amount of amelioration after a few days. Other chapters deal with the divers forms of progressive muscular atrophy, topography of the cortical centres of general sensibility, infantile, and other forms of myxœdema, &c.

(a) "Clinique des Maladies du Systeme Nerveux (Hospice de la Salpetriere)." Annee 1898-99. By F. Raymond, Professeur de Clinique des Maladies Nerveuses a la Faculte de Medicine de Paris. Quatrieme et Cinquieme Serie. 579 and 648 pp. respectively, with 136 figures and 7 Plates. Paris: Octave Doin.

The book carries with it throughout the impress of thoroughness, and of an extensive practical experience of the diseases treated therein. While recording the work of other observers, the author, whose reputation is great, has fully embodied the results of his own observations, which adds considerably to its value. Of the easy graceful style of the author, and of the good illustrations scattered throughout the work, we can but speak in terms of high praise.

OBITUARY.

SAMUEL FENWICK, M.D., F.R.C.P.

The death is announced of Dr. Samuel Fenwick, M.D., F.R.C.P., which took place on Thursday afternoon, at his residence, 29, Harley Street, Cavendish Square, at the age of eighty-one. Dr. Fenwick was born in 1821, in Northumberland, and took the M.D. degree at St. Andrew's in 1846. For some years he practised in his native county, receiving the M.D. degree from Durham University in 1859. He was lecturer on Pathological Anatomy at the Medical School of Durham University in Newcastle-on-Tyne, and on settling in London about forty years ago he was appointed Lecturer on Medicine at the London Hospital Medical College, and Assistant Physician to the City of London Hospital for Diseases of the Chest. Dr. Fenwick, who was elected a Fellow of the Royal College of Physicians, London, in 1870, was a Fellow of the Royal Medical and Chirurgical Society and a member of the Pathological Society, and was for many years Physician to the London Hospital. He was the author of many medical works and text books, among others "The Students' Guide to Medical Diagnosis," which reached an eighth edition, and "Outlines of Medical Treatment."

Medical News.

St. Thomas's Hospital.

As a memorial of their son, the late Dr. Seymour Graves Toller, Mr. and Mrs. Toller, of Scarborough, have established at St. Thomas's Hospital a prize to be maintained in perpetuity and given annually to the fifth year's student first in the examination in medicine. Dr. Seymour Toller was formerly assistant physician at St. Thomas's, and at the time of his early death in Egypt was physician to the Kasr-el-Aini Hospital at Cairo. The Governors of St. Thomas's Hospital have decided to name a new children's ward the "Seymour Ward," after their late colleague, and for its decoration Miss Jewesbury has painted eight picture panels to be affixed to the walls.

Physician's Suicide.

Dr. Stone, a well-known physician of Hull, committed suicide on the 5th inst. by taking poison. A note was found in his handwriting, containing the words: "I cannot bear scandalous reports. Good-bye all; distracted."

Expert Witness Fees.

An appeal has just been decided by the Scottish Court of Sessions in which the fees paid to a medical witness in an action for damages was challenged by the defendant railway company. The auditor had passed a fee of seven guineas, but the company urged that four guineas would have been sufficient. In the result the Court deprecated an appeal on such a trivial matter, and decided that five guineas would be a proper fee.

Catholic University School of Medicine.

In presenting the prizes, awarded in connection with the recent examinations, on Saturday last, the Dean of the School, Sir Christopher Nixon, remarked that this was now the largest medical school in Ireland, having 320 students, and had reached its present position without any recognition, financially or otherwise, by the State. The question of enlargement was now seriously engaging the attention of the faculty. He thought no Government responsible for higher education in this country could allow the Royal University to maintain its existence without a radical change in its constitution and in its relation to the colleges connected with it. In relation to medicine, it occupied a high function, and he assured his student hearers that those who held a degree from the Royal University commenced their career with a considerable bonus in hand. The prizes were:—First Conjoint Exhibition, value £12 10s., Patrick Foran; Second Conjoint Exhibition, value £10; Edward Sheridan; Third Royal University Exhibition, value £12 10s., Thomas Barry; Third Royal University Exhibition, special prize for second place, Miss Ovenden.

Contract Practice at Swansea.

The medical men of Swansea have just issued a circular putting before the members of friendly societies in the town certain points against the proposed establishment of a medical aid association. They state that they only ask for an increase from about 6s. 6d., the present average, to 8s. 8d. per annum per family.

Curious Gifts to a Hospital.

The Guest Hospital, Dudley, recently received an annoymous donation of £500 (by registered post), seven vanloads of furniture, much of it new, four pianos, and 100 pictures, the latter being valued at £350. The *Birmingham Daily Post* states that the donor is Mr. Hugh Lewis, formerly a pawnbroker of Tipton, and now residing at Sutton Coldfield.

Dublin Death Rate.

The deaths registered in the Dublin registration area for the week ending Saturday, Dec. 6th, 1902, represent an annual rate of mortality of 27·0 in every 1,000 of the population. There were 33 deaths from tuberculous disease, 15 from diseases of the nervous system, 26 from diseases of the circulatory system, and 53 from diseases of the respiratory system; 63 infants died during the week, of whom 22 were under one year old. Within the city the death rate in different districts was as follows:—Summerhill district, 38 6; Peter Street District, 30 6; Grand Canal Street district, 29·9; and Castle Street district, 51 8 in the 1,000.

London School of Medicine for Women.

The first annual dinner of the Royal Free Hospital and London School of Medicine for Women took place in the King's Hall of the Holborn Restaurant on Wednesday evening last, when upwards of 400 persons sat down to dinner, the fair sex, medical and otherwise, largely predominating. Several of the speeches were made by lady officials of the school, thus introducing a novel feature into post-prandial oratory which has hitherto been regarded as a masculine preserve. The presence of Sir W. S. Church, President of the Royal College of Physicians, may perhaps be interpreted as "a sign of the times," indeed, he formally disclaimed any feelings of hostility to the invasion of the profession by women, although he naively confessed that he had never actively fought on their behalf. Apart from the predominance of the feminine element, which was, of course, only natural, the distinguishing features of the festival were the marked prevalence of teetotal principles and the absence of the accustomed musical intervals between the toasts, an absence which was the more conspicuous in such a gathering of the fair. The success of this inaugural dinner serves to emphasise the reality and the extent of the movement, and we can well believe that it came as a surprise to some practitioners of the other sex who graced the meeting with their presence."

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed, to the Publisher.

HOSPITAL APPOINTMENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is noticeable in the list of medical appointments (last issue of THE MEDICAL PRESS AND CIRCULAR) that *five* gentlemen, whose names commence with the letter "H.," have been appointed as house surgeons or assistant house surgeons respectively to St. Thomas's Hospital. It is comforting to know the Governors of St. Thomas's, at any rate, do not drop their "H's"

I am, Sir, yours truly.
OBSERVER.

M. O.—If, as you suggest, death did not take place until more than a year after the accident, although presumably directly caused thereby, no inquest is necessary or could, indeed, be held. When the fatal result occurs more than a year and a day after the receipt of the injury it is assumed at law to be due to some other cause

EXPERT.—We cannot undertake to find out when the articles in question were published. especially as you are not sure of the titles If you will look them out and furnish us with the dates we will ascertain whether the numbers are still in print.

ANÆSTHETIST.—It is difficult to lay down any hard and fast rule as to what is or what is not fit matter for discussion in the lay Press. It is greatly a matter of taste, but the fact of the subject possessing a medical interest is not of itself a bar to public discussion. Prospective patients are at least as much interested in methods of treatment as are medical men, though obviously they may not be in a position to discuss them with advantage.

M. R. S.—As a rule it is unadvisable to give food by the mouth if rectal alimentation is being employed. The addition of a little salt to the beaten-up egg facilitates absorption. A very good formula is a egg beaten up in fully peptonised milk, to which may be added brandy or whiskey, along with a few drops of laudanum to check irritability of the bowel.

CLIPPINGS FROM LAY EXCHANGES.

A RAPID RESURRECTION.

EVANSVILLE, Ind., April 13th.—"Last night, ——, 40 years old was brought back to life by the injection into her arm of a half-pint of salt solution. The patient was taken to a local hospital for an operation, after which the physicians discovered that her heart had ceased to beat . . . . five doctors pronounced her dead. As a last resort a vein in the right arm was opened, and the salt solution injected. In three seconds the patient arose on the operating table and asked for something to eat."—*Chicago Record-Herald* April 14th, 1902.

TU QUOQUE.—We submitted our correspondent's letter to the writer of the article, who states that the facts were obtained from the report published in a local newspaper, the accuracy of which he is in no wise disposed to endorse.

H. F. M.—In Western Australia the Medical Board impose a poll tax of ten guineas on all qualified members of the profession. No such tax is imposed in Queensland or South Australia. The payments are devoted to the expenses of the Board and the prosecution of quacks, and if the latter function is properly carried out even this large demand may not be without its compensation. Here medical men pay no annual fee and they are left unprotected.

Meetings of the Societies, &c.

LONDON.

WEDNESDAY, DECEMBER 17TH.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover Square, W.).—8.30 p.m. General Meeting. Treasurer's Balance Sheet for the past Session. Ordinary Meeting. Paper:—Dr. P. Lewis (Folkestone): Convalescence. 10 p.m. Conversazione at the house of the President (Dr. Symes Thompson).

THURSDAY, DECEMBER 18TH.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Clinical Evening. Cases will be shown by Dr. W. T. Harris, Mr. P. L. Daniel, and others.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies Street, W.C.).—5.30 p.m. Mr. Cantlie: Plague. (Surgical).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—4 p.m. Clinical Lecture:—Dr. A. Giles: The Symptoms and Diagnosis of Extra-Uterine Pregnancy.

DUBLIN.

FRIDAY, DECEMBER 19TH.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Medical Section. Exhibits.—Dr. C. M. O'Brien: Cases of Lupus treated by the Finsen Method. Papers.—Dr. Joseph O'Carroll: A Case of Paroxysmal Lachycardia. Dr. C. M. O'Brien: The Treatment of Lupus by the Finsen Method. Dr. Walter Smith: (*a*) On the Occurrence of Leucine as a Bulky Urinary Deposit; (*b*) On a Reaction between Urea and Formaldehyde, and its Chemical Significance. Mr. R. C. B. Maunsell: The Diagnosis of Perforated Gastric Ulcer. Dr. G. Peacocke: A Case of Splenic Anæmia.

Appointments.

ATKINSON, HAROLD WILLIAM, L.R.C.P.Lond., M.R.C.S.Eng., Junior Resident Medical Officer to the North-West London Hospital.

BADCOCK, AUSTIN, M.B.Lond., House Surgeon to the Throat and Ear Hospital. Brighton.

BADCOCK, C. H., B.A.Cantab., M.R.C.S., L.R.C.P., House Surgeon to Teignmouth Hospital.

BLUMFIELD, J., M.D.Camb., Anæsthetist to the Hospital for Epilepsy and Paralysis, Maida Vale.

EVANS, D. HAYDN, Senior House Surgeon to the Royal Portsmouth Hospital.

HARRIS, W. J., M.B.Cantab., M.R.C.P.Lond., Physician to the Out-patient Department and Registrar of the Hospital for Epilepsy and Paralysis, Maida Vale.

HENDERSON, R. G., M.A., M.B., Ch.B.Aberd., F.R.C.S.Edin., Honorary Anæsthetist to the Liverpool Stanley Hospital.

JEFFRIES, HORACE, M.R.C.S., L.S.A., Honorary Surgeon to the Bolton Infirmary.

MYERS-WARD, C. F., M.R.C.S., L.R.C.P.Lond., Lecturer in Physiology to Charing Cross Hospital.

NIXON, JOHN ALEX., B.A., M.B., B.C.Cantab., House Physician to the Bristol Royal Infirmary.

SHERREN, JAMES, F.R.C.S.Eng., Assistant Surgeon to the London Hospital.

Vacancies.

Bristol General Hospital.—House Surgeon. Salary £120 per annum. Board, residence, &c. Applications immediately to the Secretary.

Brown Animal Sanatory Institution.—Professor-Superintendent. Salary £250 per annum. Applications to the Secretary. (See Advt.)

Essex and Colchester Hospital.—House Surgeon. Salary £100 per annum, with board, washing, and residence in the Hospital premises. Applications to C. L. Becher, Secretary.

Great Yarmouth Hospital.—House Surgeon. Salary £90 per annum, with board, lodging, and washing Must be able to give Elementary Lectures to Probationer Nurses (for which £10 extra will be paid). Applications to Richard F. E. Ferrier, Hon. Secretary, 33, Hall Plain, Great Yarmouth.

North Staffordshire Infirmary and Eye Hospital, Hartshill, Stoke-upon-Trent.—House Surgeon. Salary £120 per annum, with furnished apartments, board, and washing. Applications to the Secretary and House Governor.

Rochdale Infirmary.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing. Applications to R. W. Shaw, Esq., Southfield, Rochdale.

Royal South Hants and Southampton Hospital.—House Physician. Salary £100 per annum, with rooms, board, and washing found. Applications immediately to T. A. Fisher Hall, Secretary.

The Cancer Hospital, Fulham Road, London, S.W.—Junior House Surgeon. Salary £70 per annum, with board and residence. Applications to the Secretary. (See Advt.)

Watford Joint Hospital Board.—Matron. Salary £100 per annum, with board and residence. Applications to the office of the Board, Watford Place, Watford.

Wrexham Infirmary.—Resident House Surgeon. Salary £100 per annum, with board, washing, &c. Applications immediately to Stanley D. Edisbury, Secretary.

Births.

MAGUIRE.—On Dec. 13th, at Glengarriff, Kew Road, Richmond, Surrey, the wife of George J. Maguire, M.B., B.A.O., of a daughter.

ROWAN.—On Nov. 24th, at Lebong, Darjeeling, the wife of Major Rowan, R.A.M.C., of a daughter.

Marriages.

BATEMAN—ROBERTS.—On Dec. 11th, at the Parish Church, Lampeter, Francis John Harvey Bateman, M.A., M.B., of Heath End, Blackheath, S.E., son of Sir Frederick Bateman, M.D., LL.D., of Norwich, to Bertha Isabel, daughter of the late Hugh Roberts, of Llanwrest, N. Wales.

BROWN—VENABLES.—On Dec. 11th, at St. Mary's Church, Kidlington, John Brown, L.R.C.P., L.R.C.S.I., Knight of Grace of the Order of St. John of Jerusalem, late Surgeon R.N., Lavender Gardens, S.W., to Elizabeth (Bessie), daughter of the late James George Venables, of Oxford.

PURSER—O'BRIEN.—On Dec. 9th, at Adare Church, by the Lord Bishop of Limerick, assisted by the Rev. Lucius O'Brien, Francis Carmichel, only son of William Purser, 3, Winton Road, Dublin, to Lucy Mabel, eldest daughter of Rev. Lucius O'Brien, Rector of Adare.

UNDERWOOD.—FAIRCLOUGH.—On Dec. 11th, at St. James's Church, Barton-under-Needwood, Arthur Cressèe Underwood, M.R.C.S., &c., son of the late William Elphinstone Underwood, of the Indian Civil Service, Madras Pres., to Phyllis Maude, younger daughter of the Rev. W. H. H. Fairclough, Vicar of Barton-under-Needwood.

Deaths.

CRAWFORD.—On Dec. 12th, James Crawford, M.D., M.R.C.P., late of Ightham, Kent, son of the late Rev. Hugh Crawford, M.A., of Killashee, co. Longford.

FENWICK.—On Dec. 11th, at 29, Harley Street, London, Dr. Samuel Fenwick, Consulting Physician to the London Hospital, aged 81.

The Medical Press and Circular.

ON PROLAPSUS UTERI

WITH SPECIAL REFERENCE TO

AN OPERATION FOR REPRODUCTION OF THE SACRO-UTERINE LIGAMENTS. (a)

By E. STANMORE BISHOP, F.R.C.S.Eng.,
Hon. Surgeon, Ancoats Hospital, Manchester.

THE operation described in the transactions of the British Gynæcological Society, for May, 1901, by Mr. Bowreman Jessett, was one dealing with the sacro-uterine ligaments.

The procedure which I desire to bring before you to-night differs from the one so described, not only in some points of technique, but essentially in its aim, and the result produced. Mr. Bowreman Jessett seeks to produce, and succeeds in producing a return of the uterus to its normal level in the pelvis, and fixes it there—fixes the cervix to the sacrum behind, and the fundus to the abdominal wall in front. So long as the adhesions which he makes between these structures hold good, the uterus is rigidly retained in position, and I conceive is unlikely ever again to prolapse—but the aim and result of his operation is firm fixation with little or no improvement afterwards of the organ so fixed.

The aim of the operation I am about to describe is quite different to this; it is to obtain, as nearly as possible, a return to the normal condition, and I should like to emphasise this phrase "a return to the normal" because I believe that we have, at the present time, a right to expect such a return in these cases. It is to be noted that we have to deal in this deformity, not with the ravages of disease, leaving behind them alterations in structure which render such a return impossible, or actual losses of tissue which cannot be replaced, but with the results of injury, of traumatism, which is not necessarily followed by either of these, which leaves the parts affected in new relations to one another, it is true, but beyond this, in most cases, but little altered intrinsically, and therefore simply necessitating the repair of the results of such injury in order to restore the patient to the *status quo ante*; and this, I believe, in the majority of instances to be perfectly practicable.

Therefore we need first of all a definition of the normal uterus, and I offer this as practically useful for the purposes of this paper.

The normal uterus is one which is free to move in every direction within certain limits, but not beyond, and which is capable of development in all its parts during a succeeding pregnancy. In order to make what follows clear permit me very briefly to draw your attention to some points in the anatomy of this region. The general anatomy is, of course, perfectly well understood by all present, but there are certain things upon which fresh light has lately been thrown, and these are, I think, worth consideration.

The uterus is a muscular body with muscular offshoots, ending in tendons, the latter blending with the periosteum of the pelvis, at four points of which the two anterior are opposed to the two posterior. These muscular offshoots are much longer in proportion to their width, and so permit of the free movement of the uterus within certain well-defined limits. They are the true ligaments of the uterus, and by their periosteal attachments, they support the uterus at a normal level, and prevent prolapse. These true ligaments are the round or fundo-pubic ligaments in front, and the sacro-uterine, sacro-genital, recto-uterine, or retro-sacral (for by all these names they are described by various authors) ligaments behind.

Attached to, and swinging from, the periosteal insertions of these true ligaments to the bony pelvis, the uterus is free to move within certain limits, but not beyond. It is also perfectly free to develop in all its extent during pregnancy. If we wish to restore the uterus to a normal condition we must, therefore, so act as once more to leave it free to move within normal limits, but not beyond, and to develop in its whole extent during any succeeding pregnancy.

I need say nothing of the round ligaments. The sacro-uterine ligaments are musculo-tendinous offshoots of the uterus, and are therefore true ligaments, although small, and covered by peritoneum in such a way that their actual character at first sight may escape recognition.

Before the cervix, and with it the uterus, can descend; still more before they can be extruded as we see them in procidentia, these musculo-fibrous bands—the utero-sacral ligaments—must be weakened, relaxed, or torn through.

Besides these true ligaments of the uterus, upon the integrity of which, I contend, the maintenance of its normal position depends, there is another and broader attachment of the uterus, that namely, to the bladder, which at first sight would seem to have much to do with its retention at a proper level. But, firm as this connection is, its value is greatly discounted by the mobility of the bladder itself; an organ by no means firmly attached to its surroundings; and the posterior wall of it, to which the uterus is connected, being a structure which is continually varying in its position as the viscus of which it is a part is filled or emptied. Everyone's experience of prolapse, and still more of procidentia is that in such cases the bladder loses its own position, and is dragged downwards by the descending uterus. Indeed, the converse theorem might be far more safely held, that the bladder depends greatly for the maintenance of its normal position upon its attachment to the uterus, and through it upon these sacro-genital ligaments, than *vice versâ*. Such a theorem would obtain additional support from the fact that Professors Dixon and Birmingham describe these sacro-genital ligaments as existing also in the male. In male subjects they are attached anteriorly to the base of the bladder, and assist materially in its retention in the normal position.

The broad ligaments are usually considered, but, I confess, I think without good reason, to be among the more important structures which maintain the uterus at its normal level. We cannot rely at all upon merely periosteal attachments to prevent or restrain prolapse so that the value of the broad ligaments for this purpose is a negligible quantity.

(a) Read at the meeting of the British Gynæcological Society, December 11th, 1902.

There are certain other things, the importance of which have been very generally emphasised by authors, as more or less subsidiary factors in this question. Such are :—

1. The angle at which the uterus lies with reference to the vagina.

2. The potentiality of the vaginal canal, as opposed to the idea of an actual space beneath the uterus.

3. The action of the levator ani, pelvic fascia, and transversi perinei muscles in maintaining such potentiality, and converting an actual canal into a valvular slit in the tissues.

4. A postulated balance between intra-abdominal pressure and the external atmospheric pressure.

But, such a case as the following (counterparts of which must be in the memory of all operators here present) demonstrates that all these subsidiary factors may be absent or non-effective, and yet, so long as the true ligaments of the uterus are intact, that organ will not descend.

Mrs. M., æt. 51, a washerwoman, came to Ancoats Hospital in July of this year, with the complaint that her womb was coming down. She had had two children, the eldest of whom was twenty-seven years old. It had been a severe labour, necessitating the use of forceps, and she attributed all her troubles to this confinement. The womb began to come down, she said, as soon as she began to go about. On examination the perineum was found to be entirely absent; the sphincter ani split, and the vagina and rectum had a common opening, divided about half an inch above the skin level by a narrow band, the combined edge of the rectal and vaginal mucous membranes. There was marked rectocele and cystocele, but the finger, passed up the vagina, found the uterus in its normal anteverted position, and at its normal elevation in the pelvis. Thus, although all subsidiary factors had been ineffective for twenty-seven years, and the patient had been engaged in a laborious occupation, necessitating much standing, the uterus itself had not prolapsed, its intrinsic ligaments being intact.

Incidentally, and inasmuch as all these patients describe their condition in the same way as a "falling of the womb," this case emphasises the necessity of differentiation, for operative purposes, between true uterine descent and mere prolapse of the vaginal walls, for the latter of which conditions the operation of reproduction of the sacro-uterine ligaments is not required or suitable.

Returning to the true ligaments of the uterus, I think a few moments' consideration will show that of the two sets, the fundo-pubic and the sacro-uterine, the integrity of the latter is of by far the greater importance. Their relative shortness, the positon of their implantation below the main bulk of the uterus, their coordinate action with the vesical attachment in front, all render them more effective in maintaining the uterus in its normal position than the comparatively longer, round ligaments, which act upon the fundus. Indeed, as it were instinctively, practitioners have, in all measures short of operative interference, always acted upon these facts. Where the perineum and its contained muscular fibres are intact, and often when they are not, pessaries have been used, designed apparently with the one idea of replacing or shoring-up these sacro-uterine ligaments. I do not refer to rings or inflatable ball pessaries, which indeed are mere mechanical plugs, but to those pessaries which act upon a scientific basis—Hodge's, Thomas', and their modifications. These all act in this way, although their action has been otherwise explained and justified. They support weakened and relaxed sacro-uterine ligaments, and, if these are not torn through, the support and rest so obtained may, and indeed often does, permit of the latter's regaining their normal strength and tone, and so the patient may be cured by the use of these appliances. When these ligaments are torn, the upper bar of the instrument to some extent replaces them. In the first instance, after a certain time the pessary may be disused; in the second, it will always require to be worn, and this I conceive to be the reason why some cases will apparently be cured by pessaries worn for a sufficient length of time, whilst others can never dispense with their presence. Of course the integrity or otherwise of the other ligaments, and of the perineum, are large factors in any given case, but not, I contend, of the primary importance which belongs to the sacro-uterine ligaments.

But if this is true of cases treated by measures short of operation, how is it then that when operative interference is undertaken the importance of these posterior ligaments is so entirely ignored?

The reason, I believe, is to be found mainly in the conditions under which operations have been evolved. When first surgeons attempted to remedy this defect it was not possible, as it is now, to control all the routes by which the uterus might be reached. The sacro-uterine ligaments are deeply seated and difficult of access. Moreover, in all the old text-books of anatomy as we have seen they are described as mere folds of peritoneum. Not only is mere peritoneum useless, but to the pre-antiseptic surgeon the peritoneum was forbidden ground. It was the one structure in the body above all others to be avoided. Even in operating on herniæ, where it is now recognised as so all important that the condition of the constricted, gut should be known, the peritoneal sac in those days was opened only as a last resource, and operations were planned, and instruments such as the old hernia knife and director, constructed for that one all important purpose to avoid opening the peritoneal cavity. Naturally in those days, no attempt was made to interfere with the ligaments, and all operators busied themselves with attacks upon the uterus through the one avenue open to them, the vagina, and upon the one structure with which they believed that they could safely deal, the vaginal mucous membrane. It was not then a question as to what was the ideal treatment, it was a question of what was possible under the then existing conditions.

When an attempt was first made to shorten elongated and lax ligaments, those of which the ends lay outside the peritoneum, and could be dealt with without invading that cavity, were naturally the first to be attacked, and the operation for shortening the round ligaments was devised. In cases of retroversion or retroflexion, it has done extremely good work and will continue to do so; but it is curious to note that the importance of the genito-sacral ligaments was fully recognised by Alexander himself, who instituted this operation, although he and those who followed him made no effort to deal with them by operation. In his "Practical Gynæcology," p. 61, he says, "The Hodge, or the Hodge and stem, according to the nature of the case, are always introduced just before the operation is commenced. The Hodge should be fairly large so as to push the cervix well back and relax the posterior uterine ligaments. . . . The stem is removed at the end of the third week. . . . Where there is a weakened perineum, a tendency to cystocele or rectocele, or distinctly relaxed retro-sacral (*sic*) ligaments, the perineum must be fortified at the same time that the round ligaments are shortened, or a Hodge's or other pessary, as an inferior support, will require to be permanently worn."

Useful as this operation on the round ligaments is in cases of retro-deviation, its inefficiency in cases of prolapse and procidentia is evident *a priori* from the very conditions of the problems involved, and is equally evidenced in practice by the numerous fixations which have been in vogue of late years. A pull from the uterine cornu towards a fixed point in the pelvis on the same, or but very slightly higher, level can never raise the whole body of the uterus to any great degree; still less if the posterior supports are gone can it raise and carry backwards the cervix. It will then simply draw the uterus forward towards the pubes, and so place it in a still more favourable position for further descent. And recognising this, surgeons who had overcome by that time all dread of an open peritoneum seized the uterine body, and, drawing it bodily forward and upward, fixed it to the nearest point which offered resistance, the abdominal wall above the pubis. But such ventro-fixation materially interferes with the proper development of the anterior uterine walls in any subsequent pregnancy; and so it became a matter of great importance to show cases which in spite of this had carried a fœtus to full time development. Several such cases are now on record, but whilst it has thus been shown that such a result is possible, cases are also on record in which abortion has occurred repeatedly, others in which the resulting parturition has been greatly impeded, and others in which death has resulted. It is human nature that successful cases should be emphasised, and that those which have ended badly should be frequently unreported. The more honour to those authors who have faithfully recorded their failures; but none the less the departure from a normal condition induced by this operation and its results stands out clearly. No operator who has performed a ventro-fixation, and still less the practitioner to whose unlucky lot it may fall to attend a patient through the succeeding period of irregular dilatation of the uterus during pregnancy, and the equally risky parturition, can feel happy or secure until this severe test is well over, however triumphant they may appear afterwards. If nothing nearer to a return to the *status quo* is possible, the method with all its drawbacks may in some cases be justified—in women past the child-bearing period, for instance—but if better methods can be carried out, methods which attain more nearly to a restitution of the prolapsed organ to its original position and condition, then the supposed necessity of this plan loses it *raison d'être*.

I have myself performed a large number of ventro-fixations, and besides the objections already mentioned, another has been strongly impressed on my mind. The portion of abdominal wall to which the uterus has been attached, although relatively a fixed point, is not so absolutely. Months after the fixation has been carried out, the area of fixation will be found sunk inwards, drawn backwards and downwards by the weight of the attached organ, which will have sunk again to a much lower level than that at which it appeared at the time of operation to be located, so that the final result, even so far as the mere elevation is concerned, is not so satisfactory as at first would seem to be the case. The bladder in many of my cases also was compressed to some extent; its capacity decreased, so that the patients were troubled by undue frequency of micturition, and an inability to restrain themselves for any length of time when desire to urinate arose.

I do not mention vagino-fixation except to condemn it. I have practised it in one case, but should never again attempt it. The principle upon which it is based is, I think, false, and its results, so far as I have seen them, are deplorable. There is, moreover, one comprehensive objection to all these operations, and it is, to my mind, a very forcible if not a fatal one. Consider for a moment the symptomatology of this condition. In the very earliest period of prolapse and increasing *pari passu* with it, pain and a sense of dragging weight is felt in the lumbo sacral region. The uterus, as it descends, usually becomes more bulky, and many of the discomforts experienced are attributed to its increased weight. This is doubtless true, but for the full explanation I conceive that we must go still further back. The nerves of the uterus are derived from the inferior hypogastric and spermatic plexuses of the sympathetic system, both of which lie on the posterior concave wall of the pelvis, behind the peritoneum, and closely applied to the periosteal surface, as well as from the third and fourth sacral nerves of the spinal system. So long as the cervix maintains its normal position with regard to the posterior pelvic wall, so long there will be no tension upon these nerve filaments, but immediately that position is altered by the rupture of the genito-sacral ligaments which keep it in due apposition, tension on these nerve-fibres will commence, and increase with every degree of departure from its normal proximity to the sacrum.

Again, the veins which return the blood from the uterus, the uterine veins, follow the course of the uterine arteries. Now, it is well known that traction upon the uterus in a downward direction will so kink and narrow these arteries, that section of the uterus may be made through its entire extent without loss of any appreciable amount of blood so long as that traction is kept up, though the cut surfaces will bleed freely if the uterus is allowed to resume its normal position. The less resistant and much thinner vein wall will be still more easily affected by descent produced by any cause. As the blood current in these veins is delayed, hyperæmia of the organ must necessarily ensue, and the uterus becomes heavier still. Such increased weight leads to increased obstruction, and a vicious circle is formed, escape from which is only possible by the restoration of the organ to its normal plane and its retention there.

From this point of view a review of the various operations practised, brings out still more plainly their inefficiency.

Amputation of the cervix, which I have omitted, since I can discover no valid reason for its practice, although it may decrease the actual weight at the moment, can never re-approximate the lower part of the uterus to the sacrum, and so relieve tension in the nerve fibres supplying that organ.

And the same objection applies to any operation upon the mucous membrane of the vagina, or upon the perineum. I believe that the words I have quoted from Mr. Bowreman Jessett in the introduction of my thesis are absolutely true, and that slowly but surely, the weight of the heavy uterus above, acting as a wedge, will open up again the passage beneath, which you have temporarily narrowed, however ingeniously you may have done it: and it is evident that even immediately after operation, you have not reproduced the normal relation of the cervix to the sacrum.

The same precisely may be said of Alexander's, Olshausen's, or any of the other operations which deal solely with the round ligaments.

Ventro-fixation will certainly relieve the venous hyperæmia by taking off the narrowing strain upon the blood vessels of the uterus, but it cannot in any way replace the cervix in its normal relation with the sacrum, and so restore the nerve filaments to their normal freedom from tension.

One last operation has been practised for the relief of this condition, and surely we are justified in considering it the last effort of despair. This operation was described by Professor Edebohls, at the Manchester meeting of the British Medical Association in July. When all else fails, this operator removes the uterus, and with it the mucous membrane of the vagina down to the vulval edge. Then he unites the bared connective tissue between the bladder and urethra on the one side, and the rectum on the other by a series of purse-string sutures, beginning at the peritoneal opening, pushing this up, and placing another immediately beneath. Proceeding in this way until he reaches the skin, this also is united, and a continuous perineum is thus produced, as in the male from the anus to the urethra. He adds, very properly, that the result must be carefully explained to the patient before submitting her to this transformation.

It is, I think, evident that none of the operations I have described, and which comprise all those at present in use for the cure of procidentia or prolapsus uteri can fairly be described as producing a return to the normal condition, but that they are, on the contrary, simply substitutions of one abnormal and deformed state for another. The change may be, and doubtless often is, an improvement on the original, but it is not and cannot be a reproduction of the *status quo ante*.

As I have endeavoured to show, the genito-sacral ligaments though small, are all important in maintaining the normal position of the uterus; in cases of prolapse, and *a fortiori*, in those of procidentia they are relaxed, lengthened, and in many instances torn through. In the slighter cases, the support of a properly fitting pessary by allowing rest and time for them to recover tone, will be all that is required, but in severer instances, where they are absolutely torn through, no amount of rest will bring about their reunion. Torn muscular fibre retracts and atrophies from disuse; in the case of small muscles such as these a few months will suffice to render them practically indistinguishable from the connective tissue in which they lie. Can anything be done to replace them, to once more afford stability to the postero-inferior segment of the uterus in its normal position?

Here it is well again to emphasise the importance, if we are to restore the uterus to its normal position and condition, that it should be free to move within certain limits. If absolute fixation of the anterior and superior wall of the uterus is faulty, still more would absolute fixation of its postero-inferior segment be injudicious, since the normal descent of the cervix in parturition would be prevented, and the escaping fœtal head would find itself opposed by the immovable wall of the sacrum, coccyx, and the firm fibrous structures spreading from them both. At the same time an attachment must be contrived which will be firm and permanent. For a fixed point the aponeurotic structures covering the anterior surface of the sacrum applies a perfectly satisfactory and sufficiently broad area for choice. In choosing the particular point the ureter and rectum must be carefully avoided. Both lie over these structures, and beneath the peritoneum. Both are easily recognisable. So also are the nerve strands which form elevated flattened ridges. It is wise also to choose a point fairly free from vessels. The main vessels—the common and internal iliacs—are too far out for any uneasiness on their account. I have found that a point between the rectum on the inner side, and the ureter on the outer, is well adapted for the purpose. As to the height vertically on the surface of the sacrum, the manner of selecting this will be dealt with later. It will vary with almost every case.

In old cases of procidentia, as I have already pointed out, it is useless to search for the remnants of the original ligaments. They will have atrophied, and even if they could be found after a long and difficult dissection, the result of which would be needless damage to the tissues involved, they would be useless for reparative purposes. Whilst this is especially true in such cases, it is also true in minor cases of prolapse. Bovée, in the *American Journal of Obstetrics*, July, 1902, however, claims to have found and united the torn ends of these ligaments, both from the vaginal and from the peritoneal aspect. Personally, I believe that in every case this is a mere waste of time, and exposes the patient to needless risks. Like Mr. Jessett, I do not attempt a dissection, which must be extremely difficult, and is, from the very conditions present, foredoomed to failure; but seek to substitute something which will act in the same way, which is easily accessible, and which is sufficiently firm to be trustworthy.

It will, I think, be evident that in the upper extremity of the posterior fornix, a sufficiently firm resistant material is available, which, whilst firmly attached to the cervix, yet is of sufficient length, between its most superor point and that blended with the latter, to permit of normal movement. It is this which is utilised as the new sacro-uterine ligament.

The technique of the operation as I have carried it out is briefly this. The protrusion being reduced, the patient is placed in the extreme Trendelenburg position and the abdominal wall is opened by a median incision. As soon as the intestines have sunk away from the pelvis towards the diaphragm two threads are passed through the broad ligaments, one on either side of the uterus enclosing tube and round ligament; the ends of these threads are tied, and by them as tractors the fundus of the uterus is drawn forwards. A special sound is passed by an assistant into the vagina and made to press up towards the posterior fornix so as to render it prominent. On either side a stout thick thread is passed vertically through the substance of the fornix, avoiding the mucous lining, so that each protruding end is half an inch distant from the other and the whole loop half to three-quarters of an inch from the cervix. The fornix is now applied to the sacrum, and a spot is chosen directly opposite, free from vessels and subjacent nerves and ureter, and well outside the rectum, where the needle carrying this suture is entered deeply so as to embrace the periosteum covering the bone; it is brought out again half an inch directly above its point of entrance. Before tying this suture, a narrow strip of peritoneum is removed from that portion of the fornix which lies in its grip, so as to bare the connective tissue beneath. This is repeated on the opposite side; the sutures are tied and their ends cut short. Sometimes the position of the rectum will only permit of single fixation. This should then be more central in its position as regards the uterus and somewhat broader. The new ligament or ligaments are now formed, and the cervix hangs in its normal position from the sacrum by that portion of the vagina which lies between it and the sutures. The traction threads through the broad ligaments are now removed. As in all cases of procidentia the round ligaments have been also greatly lengthened; they are now shortened by Olshausen's method. But it is important not to shorten them to their fullest extent, so as to permit of some play still being left, so that the uterus may rise with the filling of the bladder beneath, as in the normal condition. For this part of the work Doyen's pubic retractor is very useful, giving as it does a clear view of these ligaments, and of their points of exit from the pelvic cavity. I have found it to be rather in the way in the earlier stage, so that I only introduce it after the new sacro-uterine ligaments have been made. After shortening the round ligaments it is removed and the abdomen closed. The position of the uterus and vagina is now as nearly that which obtained before prolapse began as possible, whilst the uterus itself is perfectly free to move within normal limits, perfectly free to develop in its entirety.

This manœuvre does not, of course, exclude or attempt to take the place of perineoraphy, if this should be necessary; but any repairs of this kind I prefer to carry out at a later sitting: about fourteen days afterwards if all goes well. Of all the methods by which perineoraphy can be carried out Tait's appears to the author to be the most rational, with certain modifications, but these are outside the scope of the present paper.

I have now performed this operation upon ten patients. Although the number of cases is but small, yet I conceive that they are sufficient to show not only the practicability of the operation, but the good results to be expected from it. Its claim to be a rational attempt to attack the problem of prolapsus uteri in a scientific manner will rest upon the due consideration by operators of the anatomical conditions present in these cases, and their appreciation or otherwise of the various arguments I have endeavoured to set before you. The mortality has been, and I think ought to be in all cases, *nil*, since, as I repeat, we are dealing not with a morbid but with a traumatic condition. The time is as yet too short for any evidence as to the permanence of the results obtained, and it may be said that it would have been wiser to wait until such evidence was available. As to that I believe that the operation contains within itself the essentials of permanency and now that the existence and importance of the sacro-uterine ligaments is recognised, it is inevitable that in the present era of surgical activity operations for their reconstruction will be devised all over the world.

OBSTRUCTIVE DYSMENORRHŒA.

By G. ERNEST HERMAN, M.B Lond., F.R.C.P.,
Senior Obstetric Physician to the London Hospital, &c.

Dr. Duke, in a paper with the above title, asks me a question, and expresses his disagreement with a statement of mine. The statement from which he differs is that the best local treatment of spasmodic dysmenorrhœa is dilatation by bougies. He quotes Mr. Lawson Tait, and says that he agrees with him, to the effect that dilatation "means sitting by the bedside of the patient for hours, and exercising a deal of force to the exhaustion of himself as well as the infliction of much pain on the patient."

It is evident that Dr. Duke and I are not talking of the same thing. The dilatation that I practice and advise does not occupy the surgeon for hours, or require great force, or exhaust the operator. It causes pain, which an anæsthetic will prevent. I know that in one case the effect of a single dilatation has lasted twenty-two years.

I hope Dr. Duke will not think me discourteous when I say that I do not intend to use his spiral wire stem, nor any other stem. These instruments have been in use for over half a century. Many deaths have been caused by them, and many more women have been made chronic invalids. I would recommend those curious to know the effect of treatment by intra-uterine stems to read reports of cases by Dr. Henry Savage and others, in the "Transactions of the Obstetrical Society of London," vol xxii., 1880, p. 203 *et seq.* Although these stems have been in use so long no one has ever yet published a plain account of a series of cases treated with intra-uterine stems and watched for long periods. I believe that the reason for this is that those who watch the after-history of their cases carefully enough to enable them to compile a complete table of results soon come to discontinue the use of intra-uterine stems.

I cannot agree with Dr. Duke that endometritis is commonly observed in these cases. Most cases of severe dysmenorrhœa are met with in healthy young women, in whom there is, in my judgment, no sufficient ground for thinking they have endometritis. I know that "endometritis" is a word used very loosely, and that persons may be found who will conclude that any woman with a little "whites" has got endometritis. I know also that an intra-uterine stem is a very effective cause of endometritis.

I have not used any more rapid dilator than the successive passage of bougies of increasing size. I know that there are instruments made to stretch the os uteri by forcing apart certain points in its wall, but I use them not. It is impossible to know how much force is applied with such instruments. They tear instead of stretching the cervix. Therefore I use them not.

I congratulate Dr. Duke on his ingenuity in inventing new instruments; but I think, as Sydenham did of drugs, that what we want is not new instruments, but more perfect knowledge of the effect of those we have.

THE SYMPTOMS AND DIAGNOSIS OF TUBERCULOUS PERITONITIS.

By JAMES BARR, M.D., F.R.C.P.,
Senior Physician, Liverpool Royal Infirmary.

The task set me of opening the discussion on the symptoms and diagnosis of tuberculous peritonitis is a very important one, and personally I should like to give it a much more definite and prominent position than that which it occupies in text-books. The symptoms are very vague and indefinite, and there is not one which is pathognomonic. So frequently the disease is not recognised in its early inception, nor in fact until it is well developed, and often not even until the surgeon's knife is called into play. In the present day exploratory operations are so simple, and afford such excellent opportunities for the surgeon interfering with the work of the physician, that I am afraid we do not always cultivate our various senses to the extent that we should do, otherwise we would not so frequently require the assistance of the surgeon to complete our diagnosis. We can talk very glibly about the pathology and surgical treatment of tuberculous peritonitis, but I am inclined to think that if we recognised the disease, and properly treated it in an early stage, there would be fewer cases requiring operation.

The frequent failure to appreciate the development of such an important affection is, I think, partly due to the prevalent idea that peritonitis is a disease attended by severe and well-marked symptoms, whereas we know that in tuberculous peritonitis the onset is very insidious, and often there is little or no inflammatory reaction, so that in many cases, tuberculosis of the peritoneum would be a more appropriate designation. No doubt in many cases there is a considerable amount of inflammation, but rarely, if ever, to such a degree as that associated with the introduction of other micro-organisms, such as the bacillus coli, streptococci, pneumococci, &c.; there is none of that collapse associated with paralysis of the splanchnic area, such as occurs in perforation of the bowel with escape of its contents into the peritoneal cavity, and which makes such a permanent impression on the sensorium of the observer that he is apt to overlook the milder and more chronic form of tuberculous peritonitis.

This affection may occur at almost any age, but is rare under three and over fifty, and as a rule its existence is the more readily recognised, or at least suspected, the younger the patient. Its incidence is about equal in both sexes. The disease may be acute or chronic, primary or secondary; the acute and primary are rare affections, while the chronic and secondary are comparatively common. The acute form is usually part of a general acute miliary tuberculosis, and as there is no true inflammatory reaction of the peritoneum the symptoms are submerged by the more pronounced signs of disease in the lungs and bowels. However, if the patient live long enough, attention may be drawn to the peritoneum by a slight increase in the size of the abdomen with general emaciation; there may be a small amount of free fluid in the peritoneal cavity, as in these cases the adhesions consist of a slight amount of lymph, glueing the coils of bowel together. The abdominal walls become rather tense, though there can scarcely be said to be any severe pain or tenderness, and the respirations are thoracic.

The temperature is usually rather high, and may be hectic, but that depends on the involvement of other organs rather than of the peritoneum. If meningitis terminate the scene the scaphoid abdomen does not occur.

The primary form is rare, though, like meningitis, it may occur. As a rule an original focus can be discovered at the autopsy, most frequently in the bowel or generative organs and their adnexa. I have, myself, seen the origin of a general acute miliary tuberculosis in a caseous testicle, and those who treat female diseases know what a frequent source of general infection may be found in the tubes and ovaries. The symptoms in these primary cases in no way differ from those in chronic cases, which I am about to describe.

In chronic tuberculous peritonitis the symptoms usually begin very insidiously, and as commonly the lungs, pleuræ or bowels are affected, our attention may be drawn away from the peritoneum, though in fact those primary lesions should drive our observations more closely to the significance of an enlarging abdomen.

Just as in tuberculosis of the lungs, when tuberculous ulceration of the bowel follows the prominent chest symptoms subside, so when tuberculous ulceration of the bowels is followed by peritonitis the diarrhœa and attenuated abdomen may be replaced by constipation and slight abdominal intumescence; this latter condition may give a rotundity to the abdomen which, taken in conjunction with the cessation of diarrhœa, may give rise to the erroneous impression that the patient is improving, whereas in reality the disease is extending. Pain is by no means a prominent symptom in any stage of the disease, but usually a certain amount of tenderness can be elicited on manipulation; there may not be sufficient to give rise to any expression of pain beyond that depicted on the countenance of the dull and listless patient. He is careful in his movements to avoid all jars and knocks, and when in bed is apt to lie huddled up, provided the abdomen be not much distended; these facts, coupled with thoracic breath ing, which is an early symptom in all such cases, should arrest the attention of every intelligent observer at an early stage of this affection. At first the appetite may be good, but after a little it becomes capricious and there may be vomiting. I have seen nutrition good till a fairly advanced period; but as a rule while the abdomen enlarges the rest of the body emaciates, the subcutaneous fat disappears and the skin of the tense abdomen becomes thin and shiny, so that the blue veins become very evident. Anæmia is usually marked, though this may be associated with a pink flush on the cheeks; the salivary secretion diminishes, the mouth becomes sticky, the tongue red, glazed, and denuded of epithelium, and at this stage there is considerable thirst and no appetite; the constipation and improperly digested food give rise to griping and often moderately severe colicky pains, which are relieved by diarrhoea, and this may again alternate with constipation. As the disease advances the abdomen enlarges and this is specially marked in the upper half; the umbilicus protrudes, the recti and other abdominal muscles become very tense, and the breathing is purely thoracic. The general weakness, pain and tenderness increase and the patient is confined to bed. The temperature is never very high, rarely rising much above 101° F. in the evening, and may often be subnormal, but the morning fall, even in cases of low temperature, is usually more characteristic than the evening rise. I now exhibit a few temperature charts which will emphasise these points. At this stage a certain amount of free or loculated fluid may be detected. The large and tense abdomen exhibits various degrees of resistance at different places. Coils of bowel being usually glued together, prominent tense swellings of knuckles of bowel containing gas and fæces can be readily felt. Commonly the omentum is very much thickened, and owing to the peristaltic movements of the distended bowel it gets curled up on itself, and forms a large, thick, sausage-like mass stretching across about the level of the umbilicus. The amount of effused fluid is usually small, and its location depends on the extent of the peritoneal adhesions. In some cases it is fairly free, the flanks are dull, and succussion wave easily felt. In other cases there are numerous loculi forming evident cysts which, in cases of females have not unfrequently been mistaken for ovarian cysts. I have seen a large collection of purulent fluid walled off in the lower half of the abdomen, and as the bowels are floated upon the surface of the fluid the collection most frequently takes place below the level of the umbilicus. Œdema of the lower extremities and dependent parts of the abdomen occasionally takes place, especially in adults, but this is due to the feeble and atrophic heart rather than to any excessive abdominal tension; the pulse is frequent, small and feeble. The margin of the liver can be felt about an inch or more below the costal margin. The spleen is usually rather enlarged, but not felt below the costal margin.

As the disease advances the emaciation becomes intense, the eyes are sunken, temples and cheeks hollow, countenance shows evident signs of distress, ribs stand prominently out and lower ribs partly everted by the large and prominent abdomen, and the breathing is thoracic. The skin over the chest may be dry, harsh and shrunken, while that over the abdomen is thin, smooth and shiny, and superficial veins very apparent; the umbilicus is unfolded and the recti muscles separated. The patient lies on his back or side with his knees drawn up, weakness is great, and every movement causes pain. There is often stomatitis, with a glazed red tongue and small ulcers on it and on the inside of the buccal cavity. The bowels are often loose, the motions being of a dark, watery, offensive character, and where there is much intestinal ulceration there may be blood and mucus. There is often severe griping and colicky pains accompanying the diarrhœa, but, on the other hand, cases of fatal obstruction have been observed. The temperature in late stages frequently reaches 103° or 104° F. in the evening.

Improvement in these advanced cases rarely takes place, but I have seen recovery after the evacuation of an abscess which pointed at the umbilicus, and in another case after a fæcal fistula had formed in the same situation. One of the most ominous symptoms is the occurrence of purpuric spots on the extremities and flanks.

The diagnosis largely depends on a *resume* of the symptoms which I have detailed. The slow and insidious onset, great wasting, abdominal distension, pain and tenderness, variable tension in different parts of the abdominal walls, thin stretched skin with prominent veins over the abdomen and lower ribs, and in advanced cases protruded umbilicus and separation of recto-irregular lumps in the abdomen, especially a hard, firm sausage-like mass at the level of the umbilicus forming a thickened omentum. There may be general fluctuation or evidence of cyst-like collections of fluid. The breathing is thoracic. The temperature is variable and generally marked by a morning fall. The patient looks ill, is dull and listless but always intelligent, and his senses are normal. The presence of tuberculous disease in other organs assists the diagnosis. The large tympanitic abdomen which occurs in rickets, tabes mesenterica, and dyspeptic troubles is easily distinguished by the uniform and variable distension, absence of muscular rigidity, and no great variations in the resistance at different parts, no evidence of fluid, and thoracic breathing not a prominent feature.

In typhoid fever the abdomen is often distended, but the tension is not great, and there is no muscular rigidity. The spleen is large and easily felt; the patient is dull and apathetic; his intelligence and all his senses are blunted. There is continuous fever and other typhoid symptoms which need not be enumerated. In cases of ascites arising from cirrhosis and Banti's disease the accumulation is great, the fluid is clear and of low specific gravity. In these cases there is often localised peritonitis with well marked friction fremitus, and in some cases the differentiation may cause some difficulty. The same may be said of simple chronic adhesive peritonitis arising from other causes. In some such cases I have found the injection of the peritoneal fluid into guinea-pigs of some value. As a rule patience and careful observation soon settle the diagnosis.

THE MEDICAL TREATMENT OF TUBERCULOUS PERITONITIS. (a)

By LEONARD GUTHRIE, M.A.Oxon., M.D., F.R.C.P.

In discussing the medical treatment of tuberculous peritonitis I am hampered by the prevalent notion that surgeons alone are able to cure this disease. Mr. Watson Cheyne, for instance (Harveian Lectures, 1899, p. 59), asserts that: "The prognosis of tuberculous peritonitis, when no surgical intervention has taken place, is undoubtedly very grave, but much depends on the form of the disease and on the presence or absence of complications." With the latter part of the sentence I agree, but to the former I venture to demur. It implies that the prognosis when surgical intervention has taken place is no longer very grave, and that those who do not call in the aid of a surgeon are guilty of allowing a very grave prospect to continue when it might easily be converted into one more favourable. If Mr. Cheyne's statement be accepted literally, any discussion on methods of treatment other than surgical would be a waste of time. But my own experience of tuberculous peritonitis leads me to think that the prognosis in uncomplicated cases in children is by no means so grave as we are taught to believe, and that the triumphs of surgery in curing this disease have been somewhat over-rated.

(a) Society for the Study of Disease in Children, December 12th 1902.

Of forty-one cases treated at the Paddington Green Children's Hospital, fourteen underwent laparotomy and seven of these died, whilst of the remaining twenty-seven treated medically only four were fatal. The death-rate in surgical cases was therefore 50 per cent., whilst in medical cases it was under 16 per cent. Moreover, in the four fatalities under medical treatment, the cause of death in three was septic peritonitis, due to perforation or rupture of a mesenteric glandular abscess; in one, death was due to extensive pulmonary phthisis, also present in two of the others. All of them died within a month of entering hospital, and had they undergone laparotomy they would only have increased the percentage of surgical failures. I am prepared to be told that the surgical cases were more severe than the medical which recovered, and admit the fact so far as the fatal surgical cases are concerned, but not as regards those which survived laparotomy.

It has also been urged that cases which recover under medical treatment are not suffering from tuberculous peritonitis at all. Yet it must be remembered that the diagnosis is in practically all cases made by the physician, and it seems a little hard that he should only be right when he calls in a surgeon and always wrong when he does not.

Before discussing further the claims of surgical over medical treatment I must follow the programme and deal with the latter.

Medicinal Treatment.

We cannot claim at present to slay the tubercle bacillus within the body by any drugs or anti-toxins. But the resolvent action of such drugs as mercury and iodide of potassium on tuberculous inflammations is open to discussion. Most of the medical cases were treated by mercurial inunction, or by biniodide of mercury given internally, and recovered—whether in consequence of the treatment or not is a matter of opinion. Some got well without mercurial treatment.

Arsenic.—Is arsenic of use in tuberculous affections? It is believed to cure some cases of lymphadenoma, and it is now well known that so-called lymphadenoma in children is frequently tuberculous. It would therefore be interesting to discover whether these are the cases in which arsenic is of value—for if so, arsenic might affect the course of tuberculous peritonitis. It is used extensively, I believe, in America with this object.

I know no other drugs which can conceivably have influence over tuberculosis; but by some guaiacol carbonate and iodoform are held in repute. Cod-liver oil, of course, is used systematically, but probably as food rather than medicine. Syrup of iodide of iron has a reputation, but I doubt if it is superior to other preparations of iron when anæmia is present. Medicinal treatment of tuberculous peritonitis is almost entirely symptomatic. The chief symptoms which call for treatment are pain and abdominal tenderness, flatulency and indigestion, diarrhœa or constipation, vomiting and ascites.

Pain is seldom marked in patients kept at rest in bed, unless it is due to the onset of acute septic peritonitis. The ordinary slight pains and tenderness can usually be relieved by local applications of belladonna, heated cotton wool or spongio-pilin, or in some cases by painting with iodine. Opium is seldom required.

Flatulency and indigestion need careful dieting and bismuth. *Diarrhœa*, unless profuse and continuous, needs no active treatment. In some cases it may even be salutary in reducing ascites. Bismuth and opium, or aromatic chalk and opium powder, are most useful remedies. Coto and various other astringents seem of doubtful utility. With the exception of biniodide of mercury I have little faith in so-called intestinal disinfectants. They seem to be more useful when added to the evacuations than when taken internally. Diarrhœa, when dependent on intestinal ulceration, is most difficult to control. If the ulcers are situated low down in the bowel, irrigation and astringent or soothing enemata may be of service, but when situated high up, such treatment is of little use.

Constipation.—A loaded rectum should be cleared out by enemata rather than by purgatives, but an occasional dose of castor oil, cascara, or pulv. glycyrrhizal co. may be given unless evidence of ulceration in the shape of blood-stained or black, offensive and purulent stools is present. But it must be remembered that ulceration may exist without any such evidence.

Medical Treatment of Ascites.

It is a question for discussion whether, in cases of ascites, with constipation and scantiness of urine, but without evidence of ulceration, purgatives and diuretics are indicated. I once treated such a case in this manner for a considerable time and the patient recovered. But this treatment is hardly to be recommended as a routine process.

Vomiting is seldom excessive in children at rest and properly fed, unless signs of intestinal obstruction are present which call for immediate surgical interference. When due to gastric disturbance only, bismuth and hydrocyanic acid are the best remedies.

Diet.—It is seldom necessary to feed a patient on fluids unless there is obviously extensive ulceration. The pyrexia present is rarely high enough to interfere with digestion, and harm may be done by restricting patients to the diet usual in enteric fever. One must, of course, keep indigestible substances out of the dietary. In one case, fever, vomiting and dangerous colic following a diet including green apples first drew attention to the existence of tuberculous peritonitis. Starchy and other foods, which, in excess, tend to induce flatulency and fermentation, must be given sparingly. Meat, fish, poultry, can usually be assimilated if carefully minced and prepared. Eggs, cream, milk and butter may be freely supplied. In some cases of intractable diarrhœa a diet of raw or partially cooked meat seems efficacious. When stimulants are required, brandy, if it can be procured, or old dry port from the wood, is best.

Hygiene.— In every case, rest in bed, at all events in early stages, is essential and it should be in open country air. Sometimes children have been sent into the country merely in the hope of recruiting them sufficiently to undergo laparotomy, but in a few weeks they have returned practically restored to health. Also in most of the cases which recovered after laparotomy, improvement was not manifest until the effect of country air was tried. Hence I believe that open-air treatment is even more eminently suitable to cases of tuberculous peritonitis than to those of pulmonary phthisis, and I would send all cases to undergo it under careful nursing and supervision as soon as the diagnosis has been made or even suspected. Rest in recumbent position should be maintained until all active symptoms have disappeared. Medical treatment then simply consists in keeping the patient at rest, in supplying a nutritious, fattening and abundant diet, in the relief of incidental symptoms as they may arise, and, above all, in securing the advantage of open country air.

Radical Treatment of Ascites.

The next question which arises is: When should fluid be left in and when should it be let out? In all varieties of cases it may subside spontaneously after rest in bed and mercurial inunction, but it also comes and goes whether mercury is used or not. In acute cases, unless fluid produces great distension and distress, it is inadvisable to interfere, for if removed it will speedily reaccumulate. Surgeons have discovered that laparotomy is seldom of use in such cases, but, as in some cases of pleural effusion, the withdrawal of a few ounces of fluid is sometimes sufficient to cause absorption of the rest. The supposed danger of setting up general tuberculosis by absorption of the fluid into the circulation is, I think, unfounded.

General tuberculosis is far more likely to be due to carriage of bacilli by the circulation from tuberculous caseating glands to distant parts. In more chronic cases, when fluid shows no tendency to subside it should be withdrawn. Tapping or aspiration in such cases, unless one is certain that the fluid is free, is dangerous. It is better to make a small incision and insert a blunt perforated trochar than to plunge a sharp instrument through the abdominal wall at the risk of wounding adherent intestines.

It has been said (Mr. Watson Cheyne, p. 77, op. cit.) that: "Simple puncture alone is quite ineffectual." But four cases in which the fluid was free and excessive recovered after being so treated, and in only one of these was it found necessary to repeat the process, and then only after a lapse of one year. It is, however, sometimes ineffectual, and the case should then be treated by simple incision or laparotomy. This is the operation which is supposed to have revolutionised the prognosis in tuberculous peritonitis.

It is of the simplest character. The surgeon makes a two-inch incision through the abdominal wall, lets out any fluid which may be present, calls upon the bystanders to observe the resemblance between a tuberculous peritoneum and a sago pudding, and then closes the wound. It is no longer considered necessary to irrigate the peritoneum with or without antiseptics, nor even to break down adhesions unless they are causing obstruction. The surgeon, like an ancient Etruscan Haruspex, merely gazes at the victim's entrails, and then discovers propitious omens for the future of abdominal operations.

Many fanciful theories have been invented to explain the recovery of 50 per cent. of cases after laparotomy. The entrance of light, air, oxygen and non-pathogenic organisms has been held by different theorists to effect a cure. Mr. Watson Cheyne believes that the tuberculous fluid evacuated is replaced by anti-bacteric serum inimical to the tubercle bacilli. If this is so, a similar result should follow simple puncture, and perhaps it does, although the procedure has been regarded as quite ineffectual.

I believe, indeed, that there is no mystery whatever in the matter, but that simple laparotomy is useful only in so far as it lets out the fluid. Dry cases, which are supposed to be cured by the operation, would, I believe, recover equally well if left alone, provided that no complications, such as extensive ulceration, septic peritonitis (due to suppuration of glands or perforation), meningitis, or advanced pulmonary phthisis occur. Indeed, the recovery of uncomplicated dry cases not operated upon compares favourably with that of laparotomy cases, whose convalescence is retarded by abscesses and fistulæ arising from tuberculous infection of the operation scar. On the other hand, surgical interference is absolutely necessary in cases of obstruction by adhesion bands and stricture, and in cases where suppuration is suspected; and when acute septic peritonitis from perforation or rupture of an abscess occurs, an operation is the only chance, though a forlorn one, of saving life. Finally, I believe that caseous mesenteric glands should be removed if possible as being the chief source of fatal dissemination. It will be observed that in all these cases something more is necessary than merely opening the abdomen and looking inside. Unfortunately, the cases in which more is necessary are those which make the mortality of the operation as high as it is; whilst the more favourable results of foreign observers are, I believe, due to operating upon cases which would get well without.

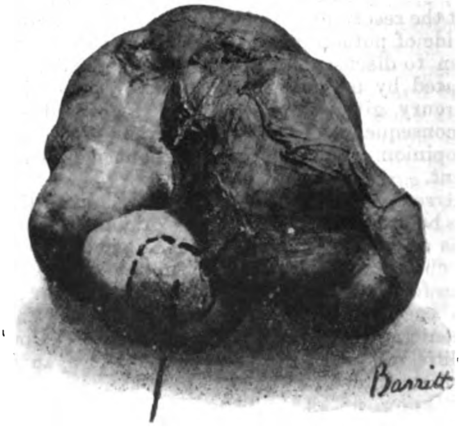
In conclusion, we owe a debt of gratitude to surgeons who, through fortunate errors in diagnosis, have taught us that conditions once held to be incompatible with recovery are by no means necessarily fatal. Those who advocate indiscrimate operations may be reminded of the well-known story of Ambrose Paré, the celebrated French surgeon. Once after a battle he ran short of boiling oil, and could not sleep for thinking of the sad plight of the wounded who had not received their share. But the next day he found them infinitely the better for being without it.

Clinical Records.

ILLUSTRATIVE CASES OF GYNÆCOLOGICAL SURGERY.

By Robert O'Callaghan, F.R.C.S.I.,
Surgeon to the French Hospital, London.

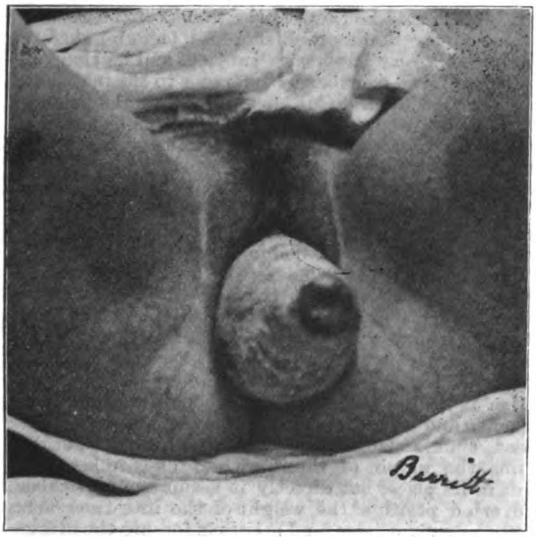
Case 1.—*Fibroid attached to the Liver removed by Hysterectomy.*—The large crop of fibroids shown in the photograph were removed from a single woman, æt. 39. When admitted into hospital it was at first thought she was suffering from acute hepatitis, which, however, on palpation proved to be an attack of localised peritonitis connected with one of these fibroids, which was securely attached to the liver by old adhesions, there being a short, thick pedicle between this fibroid and the main crop; it appeared at first to be a separate growth and hepatic in origin; bimanual examination, however, proved the tumours to be all of the same nature, and uterine in origin; they filled up the pelvis and abdomen so completely that one wondered how the poor woman had been able to earn her living as a general maid, and how the different organs involved in the pressure were able to do the work, and yet until this very acute attack



Fibroid Adherent to Liver.
Point of Adhesion, Posterior Surface.

she had not been ill enough to give up her work for ten years, dyspepsia and constipation being her only troubles, besides profuse losses at her periods. After consultation with Dr. George Ogilvie, whose patient she was, we decided that operative interference was the only means to enable her to earn her livelihood again. On opening the abdomen by a large incision, extending an inch and a half above the umbilicus, I found that this one fibroid was firmly attached to the liver, and on palpation was apparently part of it; it was also adherent to the hepatic flexure of the colon and great omentum. The rest of the tumours filled up the whole abdomen and were adherent everywhere. It required considerable force to peel away the hepatic attachment, which was followed by smart hæmorrhage; this was treated by packing with large, hot sponges while delivering the remainder of the fibroids, one of which was firmly wedged like a child's head in Douglas's pouch, and adherent. After delivery I removed the whole crop by hysterectomy, also the ovaries and appendages. After the peritoneal toilet was finished I then removed the sponge packing, but as there was still some considerable oozing I left a glass drain in Douglas's pouch for twenty-four hours. The patient had a smart attack of localised peritonitis in the hepatic region forty-eight hours after the operation, which, however, yielded kindly to three grains of calomel followed by a seidlitz powder and a turpentine enema. She went to a convalescent home in five weeks, and is now, nine months after operation, fat and well, following her usual occupation.

Case 2.—*Hysteropexy for Complete Procidentia in Single girl, aged Eighteen.*—M. A., single, æt. 18, was admitted into hospital with the condition you see in the photograph—this of two years' standing. Two years previously when working in the fields she lifted a heavy pannier, and while doing so she felt something suddenly protrude between her thighs; the poor girl was so frightened and ashamed that she kept her condition secret, never even telling her mother; left her home and came to London, where she worked for her living with this fulsome condition of things existing, until at last the pain and scalding caused by the urine and discharge voided over her excoriated thighs and ulcerated mucous membrane drove her to confide in her mistress, who brought her to the French Hospital. It is hardly possible to conceive that such a condition of things could exist undetected in this country for two years. After a few days rest in bed, the parts, having been treated by boric fomentations, were easily reduced, and after a fortnight's local treatment I opened the abdomen just above the pubes and anchored the uterus to the peritoneum by two deep silk ligatures passed through the upper and posterior uterine wall, which caused an anteflexion of this organ, thus tilting the cervix backwards and upwards, giving a maximum tension to the vaginal walls. The operation is a perfect success, and the patient is now able to go about and work with her uterus and vagina in their proper site—nine months after operation.



Complete Procidentia

Remarks by Mr. O'Callaghan.—The special point of interest in Case 1 is that it shows that a fibro-myoma can become attached during its life to the liver. Up till lately pathologists thought that it was not possible for these tumours to become attached even to the small intestine. Now we know better, and find them like parasites, forming strong adhesions to any, or all of the viscera, and as I have on a previous occasion pointed out can live entirely upon these adhesions after complete strangulation of their pedicle by torsion. As far as I can learn from literature on the subject, this is the first case of fibroid attached to the liver that has been recorded. It is also worthy of note that large tumours such as these can be carried about by a woman for many years without her even suspecting anything abnormal in her interior economy, as in this case. A severe attack of gastro-enteric influenza was the principal cause of the acute symptoms, and was what she came in for.

In Case 2 we have also a unique record, that is, as regards the age of the patient, as I cannot find any evidence of such a condition reported as occurring in a girl of this age. The misery, both mental and bodily, that this poor girl must have silently endured for two years can only in some way be realised by a glance at this photograph. I had hoped, when opening the abdomen, to find some cause for this unusual condition of things in a young girl, but found nothing abnormal. I stitched the uterus to peritoneum only, as I consider this makes an easy and mobile attachment for the uterus to swing from, and in case of pregnancy in the future gives more room for it to rise out of the pelvis.

In those cases in which I found this operation necessary after the menopause, I fix the uterus firmly to the muscle and tendon in the abdominal wound, and if the anterior wall is much prolapsed, I fix the uterus up, completely retroflexed, by inserting the sutures as low as possible in the anterior uterine wall. In conclusion, let me say that, in my opinion the time has now come, when pessaries, of whatever kind or description, should be for ever discarded in the treatment of these cases, and they should be dealt with by some form of abdominal fixation.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY.

Meeting held Thursday, December 11th, 1902.

Dr. Heywood Smith, a Vice-President, in the Chair.

Dr Macnaughton-Jones showed a series of specimens of myomata exhibiting the different morphological features of these growths. The question arose from Dr. Snow's specimen of monoma shown at the last meeting as to the dual nature of that tumour. In the specimens he (Dr. Macnaughton-Jones) now brought for inspection all the usual forms of growth were seen. In one the single fibro-myomatous growth involved the entire uterus, the canal of the latter being obliterated and the section of the growth showing a dense fasciculated and reticulated structure; in this instance the whole tumour preserved an exceptionally red appearance. In another, the growth, of a similar nature, is seen to compress the uterus laterally, obliterating the canal in this manner. Still, the tumour is a single one; there is, as in the last, but little capsule, and there is only the serous envelope covering the interstitial growth. In another specimen is seen a different condition. The uterus lies in the centre, and there is a growth, encapsuled and symmetrical in character, at either side of the uterus compressing the canal between the two, and these bilateral growths are encapsuled. Any of these growths before section would give the idea of a single myomatous growth. Here, however, was an interesting specimen of a comparatively small myoma of an oblong nature, which had only recently been examined, so hard that it had to be cut through by the aid of a hammer. In it the canal of the uterus (removed by supra-vaginal hysterectomy) was lost in the growth, which exhibited two isolated nodulated growths of the same size, which had evidently grown in centrifugal fashion with consecutive laminæ, encapsuled and separated by some distance from the serous covering. In the drawing of another such tumour, also apparently of a single myoma, five of these interstitial growths were seen embedded in the substance of the tumour. In one of these specimens a few small subserous growths were beginning to sprout. On the other hand a typical example of the subserous and submucous multiple myoma was seen in the large tumour exhibited. In this, if the separate growths were all counted, from those of the size of a large orange to those of a pea, there could not be less than a hundred. In this case the uterine canal was hollowed out into a large cavity; mucoid degeneration had still further increased its size and the separate outgrowths had taken the direction of least resistance, either submucous or subserous. A few were pedunculated. In the most interesting specimen he had before shown at the Society they would see that the uterine canal was greatly enlarged and disintegrated by mucoid degeneration, while above it the large subserous myoma was of the ordinary type, but the distinct growth below, which grew from the cervical region, had degenerated into a necrotic mass in the centre, surrounded by a calcareous zone inside the capsule of the tumour. The question of interest was, how these interstitial, nodular and isolated growths began; what relation did they hold to the original morbid process? were we to regard them as separate tumours, and speak of them as such, or were they secondary formations arising from some pathological accident or occurrence in the original growth, as, for example, an infarction, or a vascular degeneration, as contended for by Mr. Stanmore Bishop? A centrifugal growth arising around an old extravasation and a resulting hyperplasia might explain their appearance, but this was a question rather for the histologist and pathologist.

Mr. **Robert O'Callaghan** contributed notes of a case of "Hysteropexy for Complete Procidentia," which will be found under "Clinical Records" on page 683.

Dr. C. H. F. **Routh**, commenting on the possible etiology of such a displacement, referred to two cases in young unmarried women in which prolapse recurred after repeated operations, and in which, from the observation of the nurses, there was reason to suppose that vicious interference with the genitalia, on the part of the patients themselves, might have been a factor.

Dr. **Macnaughton-Jones** thought the operation described quite inadequate for the cure of the condition shown in the photograph; if the uterus had been fixed to the fascia of the abdominal wall there might have been a chance. It would be interesting to hear the further progress of the case, as the patient did not appear to be wearing any support. As a rule, in his experience, such cases were not cured without some cicatrisation to the abdominal fascia.

Dr. **Herbert Snow** had had such excellent results after anchoring a prolapsed uterus in a young married woman to the cicatricial tissue left by a previous cœliotomy as to suggest the idea of artificially creating such tissue as a seat for the fixation of the uterus.

The **Chairman** (Dr. Heywood Smith) concurred with Dr. Macnaughton-Jones that mere suspension to the peritoneum was absolutely insufficient. He believed he had himself been the first to fix a uterus to the abdominal wall, and had been very severely criticised at the time for doing so, but ventral fixation came to be very frequently done in operations for ovarian disease a good many years ago. Howard Kelly and some others strongly recommended that the sutures should be passed through the anterior, and not, as Mr. O'Callaghan had done, through the upper and posterior wall of the uterus. The best position for the suture was an important question in reference to the development of the womb in any subsequent pregnancy.

The **President** showed a cirrhotic ovary removed from the left side of a nurse, æt. 24; the other ovary, though also affected to a lesser extent, on account of the patient's youth, had not been removed. Menstruation had been established at the age of 14, and had been regular till a year before he saw her, when it began to come every three weeks and to last for six days; but for the last two years she had had very severe pain in the left inguinal region before and during the flow. There was some tenderness on the left side, but no evidence of enlargement of the uterus; she had been curetted without any good result. He had diagnosed the case as one of cirrhosis, as on operation it proved to be, but the specimen was peculiar: in ordinary cases of cirrhosis the fibrous tissue was deposited round the blood-vessels, and the stroma contained cysts so that the outer surface became corrugated; this ovary was quite smooth, its envelope, though not very thick, was extremely dense and firm, so that the increased local circulation at the periods set up a very tense condition attended with great pain. After the operation the patient suffered from chloroform sickness for nearly a week, and, probably from strain, a swelling formed in the left side, which he took to be a hæmatoma, and which subsided under the administration of perchloride of mercury. He was sorry to say that when she left London she had still some pain in the left side, and the question suggested itself whether it might not have been better to have removed both ovaries, and whether the pain was merely in the stump and would subside as the post-operative hyperæmia decreased, or was sympathetic and due to the cirrhotic ovary left on the right side.

Mr. **Stanmore Bishop** then read a paper on "Prolapsus Uteri," which will be found under the heading of "Original Communications."

Mr. **Jessett** said he thought the thanks of the Society were due to Mr Stanmore Bishop for bringing before its notice this very important subject, and he thanked Mr. Bishop for so courteously referring to the fact that, in a paper read by him (Mr. Jessett) before the Society last year, attention was drawn to the importance of restoring the utero-sacral ligaments when operating for prolapse or procidentia of the uterus. In discussing this subject, it is important to consider the reason of the uterus dropping. I think it will generally be agreed, as Mr. Bishop has pointed out, that the fundo-pubic ligament and the attachment of the uterus to the bladder have very little to do with keeping the uterus in its normal position, and that on the contrary the bladder may often be one of the primary causes of prolapse of the uterus, acting mechanically, for if the bladder is frequently allowed to become over-distended, by keeping the uterus in more or less a vertical position it throws an extra strain upon the utero-sacral ligament, and this strain becomes the greater if the patient suffers from constipation. In the normal position the weight of the intestines tends to keep the uterus in its place, but directly it assumes a vertical or retroverted position, the weight of the intestines acts directly as a *vis a tergo*, and assists in forcing the uterus downwards into the vagina. Those were the arguments that induced me in the first place, when performing ventral fixation of the uterus, to urge the necessity of restoring this important ligament. Most gynæcologists who have practised ventrofixation for prolapse have, I take it, experienced the disappointment that often attends their efforts. Sooner or later, in many cases, the attachment to the abdominal wall will become elongated and stretched, and the uterus will gradually prolapse again. Now this trouble can only be overcome by restoring the hinge or sacro-uterine ligament, thus slinging up the uterus posteriorly and allowing it to assume its normal position. Mr. Bishop rightly interprets my views. However, as I have not at present trusted entirely to the shortening of these ligaments alone for the retaining of the uterus in its proper position, and, so far as I can gather from his paper, neither does he, as he shortens the round ligaments, and also repairs the perineum, so that so far we both agree. Mr. Bishop's operation, however, differs from my practice in so much that when I have placed the patient in the extreme Trendelenburg position and drawn the uterus well forward, an assistant passes a long pair of forceps into the vagina, pushes the posterior fornix firmly up, and by opening the blades puts it upon the stretch; avoiding the vaginal mucous membrane, I then, by means of a darning stitch, pass two or three sutures in and out through the tissues as often as the length of the elongated and stretched fornix requires, commencing at each side of the rectum, and finally catching up the muscular tissue of the uterus nearly opposite to the internal os, tie each suture firmly, but not too tightly. If the round ligaments are very much stretched I prefer to double these upon themselves and secure them with two or three fine silk or chromic gut sutures. I have never trusted entirely to the shortening of the sacro-uterine ligament, as although the hinge is restored, yet I should fear that should the perineal support be weakened and left unrepaired future trouble would result. This is evidently Mr. Bishop's view also, as in the two cases he reports perineorrhaphy was also resorted to. In many slight cases, however, I can quite realise that the restoring of the sacro-uterine ligament would be quite sufficient to keep the uterus in its position. When the cervix is greatly hypertrophied it may be necessary to amputate the hypertrophied portion, as well as to perform perineorrhaphy, but to discuss this would be outside the scope of Mr. Bishop's paper. One method of shortening this ligament was alluded to by Mr. Bishop in regard to those cases which can be attacked through the vagina. I have in two severe cases of procidentia operated in this way by reflecting a diamond-shaped strip of mucous membrane from the posterior vaginal wall with the apex of one end at the junction of the mucous membrane with the uterus. I then unite the deep muscular edges by passing a Chinese gut suture deeply, with a curved needle uniting the two extreme points of the divided parts at the cervix uteri and sacral point, catching up the tissues in one or two places according to the length of the denuded surface to be shortened, and ending in the aponeurotic tissues at the side of the rectum. Two other sutures are passed similarly, first on one side, then on the other, and tied, thus uniting the extreme points. The mucous membrane is then united by a continuous ten-day gut suture transversely, so burying the deep sutures. By this operation it will be seen that the os and cervix are drawn completely up to their normal position. The incision in the vagina, which was made longitudinally, becomes transverse. Since performing this operation I have read Bovée's interesting paper (*American Journal of Obstetrics*, July, 1902). He says the ligament can be brought plainly into view by careful dissection; I hardly think this is necessary. He also shortens the round ligaments through the anterior fornix. In neither of my cases did I do this. I finally perform perineorraphy if necessary. One case was that of a very stout lady, who was quite incapacitated from taking any exertion in the way of walking, gardening, &c. Now she can bike and ride, and enjoy her life better than she has done for years. In very severe cases I certainly should feel it safer to adopt ventro-fixation as well as shortening the sacro-uterine ligaments. In such cases I think every object would be met by ventro-fixation by means of a suture of ten-day catgut, passed through the peritoneum and transversalis fascia only, so that practically there would be merely a peritoneal ligamentous attachment connecting the anterior surface of the uterus to the parietis. This would get over the objection which Mr. Bishop very properly raises of the fixation of the organ by the combined operation of ventro-fixation and shortening the sacro-uterine ligaments. I would strongly urge upon Fellows who are constantly having these distressing cases brought to their notice to give the suggestion so admirably described by Mr. Bishop in his paper, and described and practised by myself, their careful consideration, and also to read his paper alongside of that published by Bovée. I am convinced that the principle is good, but doubtless the details of the operation require much perfecting, and I shall hope in the future to find that some of the distinguished Fellows of this Society will in the near future be able to report the relief of many poor women whom they hitherto had looked upon as hopeless invalids.

Dr. Macnaughton-Jones said that it was only right to remember that Schultze had over twenty years ago entered fully into the part played by the retro-uterine and utero-vesical folds in the production of retroflexion and prolapse. In fact, his entire treatment of these conditions was based upon the part taken by these structures in maintaining the uterus in its normal position. Very little had been added to our knowledge of the etiology of prolapse since Schultze wrote on it. Before adopting a new procedure we should contrast it with other operative measures which might be suitable in cases in which it was not indicated. For his part he believed that the important point to press in regard to prolapse was its prevention rather than its cure. The recognition of the early stages of prolapse, and the causes which were contributing to its occurrence, enabled us by proper palliative measures and simple operative steps to anticipate and prevent it. Thus more serious and extensive operations were rendered unnecessary. It was certain that by other operative procedures than that advocated by Mr. Stanmore Bishop most satisfactory and permanent cures were effected. Everything depended upon the stage and degree of the prolapse. Referring to some of these procedures, he said that different operators were wedded to the methods which they practised themselves, but which others had abandoned, for example, to vaginal colpotomy with fixation, which Mr. Bishop would altogether discard. Such an expert as Auguste Martin, of Greifswald, who must have treated many hundreds of these cases, always operated by vaginal fixation, and at the same sitting, if necessary, also performed anterior and lateral colporrhaphies, perineorraphy, and amputation of the cervix, operation in every case being preceded by curettage.

After a few remarks by Dr. Routh, on the suggestion of the Chairman the discussion was adjourned to a future meeting, Mr. Bishop reserving his reply.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Surgery.

Meeting held Friday, December 12th, 1902.

The President, Mr. L. H. Ormsby, in the Chair.

Mr. E. H. Taylor on a case of

CISTIC TUMOUR OF THE BRAIN.

The patient, a man, æt. 32, had enjoyed good health up to March, 1901. Subsequent to this date he began to experience progressive weakness in his left lower extremity, which extended upwards so as to involve his arm and his face, also on the left side to some extent. Sensation was somewhat dulled on the paralysed side. There had never been any convulsive attack or giddiness. The classical symptoms of intracranial pressure were very marked, viz., optic neuritis with progressively failing sight, frequent and paroxysmal headache and vomiting. The diagnosis made was that of a subcortical tumour in the right cerebal hemisphere and in the vicinity of the motor area. Operation was performed on April 26th, 1902. A large omega-shaped flap, 3 ins. by 3 ins., was raised, including the scalp and the subjacent bone: two-thirds of the flap lay in front, one-third behind, the line indicating the fissure of Rolando or the sulcus centralis. In the process of elevating the bone a number of small trephine holes were made and the intervening bridges of bone divided with Gigli's saws. The dura when exposed was very tense and did not pulsate. On dividing the membrane and turning it aside, the brain bulged into the opening in an alarming fashion. No tumour was visible nor could be felt; fluctuation, however, was very evident quite close to the brain surface. An incision made through the cortex permitted the escape of a quantity of clear straw-coloured fluid, the result being that the brain instantly collapsed and receded very considerably from the inner aspect of the cranium. A sterilised soft rubber tube, introduced into the cavity for drainage purposes, could be pushed easily in different directions revealing a cavity of some magnitude. The bone flap and dura mater were replaced, and the tube brought out through one of the trephine holes at the posterior margin of the flap. Meningeal hæmorrhage caused some trouble and delayed the concluding steps of the operation. Patient bore operation well. There was temporary paralysis in the left arm for some time afterwards; however, the after-course of events has been satisfactory; the left lower extremity has recovered its power, so also has the upper extremity. The patient is able to perform his regular work as well as usual, and has never had any symptoms of headache or vomiting since the operation. His sight has also improved. An interesting feature of the case is that more than three months ago a slight convulsive seizure occurred in the left arm suggestive of the onset of Jacksonian epilepsy; for this the patient was put on fairly large doses of bromide of potassium. His general health is excellent at present, and according to his own statement he has never been better; his vision, too, has improved. The last observation as to the patient's condition was made on November 28th, seven months after the operation.

Dr. **Maunsell** said that he thought that the fracturing of the base of the bone flap was not right. It would be better if it were first nearly sawn through with a Gigli saw.

Sir **Thomas Myles** in a case of glioma had found the introduction of the Gigli saw very difficult; it had, however, the merit of causing little or no bleeding. Sir Thomas explained why Mr. Maunsell's method was not applicable. He thought it was impossible to make a differential diagnosis between a cystic tumour and a glioma.

Dr. **Haughton** said that if the centre of motor disturbance was located it might have been better to make a small trephine hole over the tumour, introduce a small needle and ascertain if it were a fluid tumour. This method would not cause much brain disturbance and would give the necessary information.

The **President** detailed a case of abscess of the brain he had recently operated on with good results.

Mr. E. H. **Taylor** said his own experience was that the bone breaks cleanly across. If a spicule did appear it could easily be snipped off with a forceps. The difficulties in brain tumours were three in number. 1. Diagnosis. 2. In what part is tumour situated? 3. Is it capable of being removed? With regard to the trephine holes, he said if he were doing the operation again, he would just make two and make vertical sections on each side with the forceps. With regard to anatomical measurements he said he thought it desirable to define approximately the underlying portions of the cortex. He formed a depressed fracture situated near the motor area. He did not approve of Dr. Haughton's plan of trephining a small hole and putting in a small syringe.

Mr. R. C. B. **Maunsell** read a paper on

TWO UNUSUAL CASES OF NEPHRECTOMY.

The first case was that of a female infant of sixteen months, from whom he removed a congenital cystic kidney which weighed 3 lbs. 2 ozs. and measured 22 by 16 ins. in circumference. The child made an uneventful recovery. Mr. Maunsell advocated ether as the anæsthetic for children, and gave his reasons for choosing an oblique incision commencing at the eighteenth intercostal space and sloping to the middle line below the umbilicus, the sheath of the rectus being opened without cutting the muscle fibres. The second case was one of pyonephrosis, complicated by subphrenic abscess following occlusion of the ureter. Mr. Maunsell treated it by Ollier's subcapsular nephrectomy, and gave reasons for this choice. The pathology of the cystic kidney was then discussed and it seemed to support the theory of an origin in fœtal papillitis.

Mr. **Taylor** thought the subcapsular method of securing the kidney very useful in some cases.

Mr. **Lentaigne** said that he had found the subcapsular method of operation very easy in a case of tuberculous kidney without perinephritis. He related a case in which he had drained both kidneys for calculous pyelitis with complete success.

Mr. **Gordon** said that in these congenital cystic kidneys that the affection was bilateral, and one would fear that the second kidney might become inefficient. He considered the incision from tip of the last rib towards the sheath of the rectus a very good one.

Dr. **Wayland** said that as regarded anæsthetics for children he agreed with Mr. Maunsell that ether is better than chloroform. There were only two drawbacks to ether: 1, it was more unpleasant; 2, there was a liability to accumulation of mucus. Both these were only temporary, and the second one ceased soon after commencement of operation.

Mr. **Maunsell**, in replying, said that the reason he performed nephrectomy in this case was that he knew the history of the case, and that there was no chance of the ureter becoming pervious. Besides, the patient was moribund from cancer. He thought the sub-capsular should be the primary operation in such a case, as the pedicle could be got at in case of hæmorrhage. He said he always gave ether to children, even in removing tonsils and adenoids.

The Section then adjourned.

France.

[FROM OUR OWN CORRESPONDENT.]

Paris, December 21st, 1902.

TREATMENT OF PSORIASIS.

Prof. Chauneil recommends the following treatment: The patient should be advised to reduce his animal food and follow as much as possible a vegetable diet, abstaining from strong cheese, alcohol, and fermented liquids generally. Lithia or alkaline waters were of use, especially when taken at the springs. Regular corporeal exercise had an advantage of keeping the skin in order.

The internal medication usually employed is arsenic, iodide of potassium, and the dried thyroid gland. Of the former, Fowler's or Pearson's solution, or, again, the waters of La Bourboule, were generally given. Four to six drops of Fowler's solution at each repast, increased every two days by one drop until twenty drops were reached, constituted an excellent method of taking the salt. Pearson's solution may be given in double that amount, while the Bourboule waters might be given from one to three glasses daily.

Iodide of potassium should be given in large doses, commencing by one drachm daily to three drachms. It is recommended to drink a glass of water after each dose to prevent gastric intolerance. The treatment should not exceed one month.

He considered ingestion of the thyroid gland dangerous.

The external treatment was much more important. The first thing to be done was to remove the scales by a warm alkaline bath, somewhat prolonged, during which the patient rubs himself vigorously with a brush and soft soap.

The following applications may be employed:—Vaseline, lanoline, axunge, are adapted to persons whose skin is very fine and sensitive. Oil of cade is in very general use; it is prescribed under the form of glycerol.

Weak—

℞ Oil of cade, ʒij.;
Soft soap, q.s.;
Glycerol of starch, ʒiij.
Ess. of cloves, q.s.

Strong—

℞ Oil of cade, ℥iss;
Soft soap, q.s.;
Glycerol of starch, ʒiss;
Ess. of cloves, q.s.

Pyrogallic acid can only be employed on small surfaces on account of possible intoxication, as evidenced by a dark olive-green colour of the urine.

Chrysophanic acid gives rapid results; the strength is one in ten. As in the case of pyrogallic acid, the surface presented to the ointment should be very limited. Mercurial preparations, naphthol, salicylic acid, are used by some with much success.

R Vaseline, ℥iiij;
Pyrogallic acid,
Chrysophanic acid,
Ichthyol,
Naphthol,
Salicylic acid, āā ʒss.

Glandular Fever.

Glandular fever, says Dr. David, is not well known, in spite of the articles published on the affection by Mérigot and others. It follows almost always an infection of the tonsils and the pharynx in children. Its principal symptoms are: More or less intense fever, lasting from three to four days; the glands of the neck on both sides become swollen and painful, and in the course of the affection other glands become infected, such as those at the roots of the arms and legs, of the mediastina, and in the mesentery. The glands, except under very rare conditions, never suppurate. This curious affection may be attended with serious complications—swelling of the liver, spleen, epistaxis, albuminuria, otitis, and general septicæmia. The malady gets well by ordinary hygienic treatment. Quinine seems to have no effect on the fever.

Bovine Tuberculosis.

Dr. Borrel, of the Institut Pasteur, to whom Dr. Garnault appealed to investigate the experiment he was carrying out on himself to prove the transmissibility of bovine tuberculosis to man, has just drawn up his report. As might have been anticipated, Dr. Borrel does not find himself in a position to formulate any definite conclusions, although he gives a guarded support to Dr. Garnault's views. Professor Koch's statements will require much more protracted, extensive, and careful experiments than these to establish either their trustworthiness or the reverse.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, December 20th, 1902.

At the Medical Society, Hr. Gutmann showed a patient suffering from

Gumma of the Retina.

A conical projecting black speck was to be seen between the retina and the macula lutea, by the inner side of which a distinct white tumour was visible. In the immediate neighbourhood were blood-specks and white exudations and changes in the other parts of the retina and arteries. The patient denied having had syphilis. Specific treatment had been begun, however, and the tumour was becoming less prominent.

Hr. Rosenstein showed the urinary organs of a man who had been admitted into hospital in an unconscious condition. For years he had suffered from bladder troubles. Two days before he had been attacked with nausea and vomiting, and later on, loss of consciousness. Then complete aneuria came on. Catheterisation failed, and puncture of the bladder was only partially successful, for when the patient was admitted the bladder extended to the umbilicus. A vesical fistula was made, but the patient died in a state of coma in twenty-four hours. The autopsy revealed excessive hydronephrosis, hypertrophy of the prostate, and four false passages.

Cadaveric Fatty Pneumonary Embolism.

Hr. Westenhoeffer reminded the members of his remarks the previous year on frothy liver, and observed that all frothy organs were cadaveric formations. The deficient nucleus colouring depended on chemico-physical, not on biological, processes. In June this year he had again the opportunity of doing a *post-mortem* on a body with frothy organs. It was that of a woman after abortion who had been feverish for six days, and who died the day after her admission into the Charité. The section was made eleven hours after death, and all the organs were found emphysematous. The heart, which, after ligation of all efferent and afferent vessels, was opened under water, and air escaped, and fat at the same time. Fat was found also in the capillaries of the lungs. Whence the fat came an examination of all the organs did not at first reveal. As the larger vessels of the lower extremities were opened, however, fat was found in both femoral veins, which welled up out of the deep femoral on pressure. This pointed to the bone marrow. This in both femora was completely split or broken up and discoloured, and Fraenkel's gas bacillus was easily found.

The speaker believed that this must during death have found its way into the blood-vessels. The gas production must have taken place after death. A further condition was that red marrow must be present, because in white marrow the bacillus would not develop sufficiently as it was but poor in albumen.

Fistula of the Urethra and Cancer.

Hr. Lipman-Wulf related the case of a man in the fifties who fell astride on to the angle of a trunk and hurt his urethra. After two months there was trouble in micturition, and a tumour formed on the perineum. Urethrotomy was performed, and several small abscesses were found, but the fistulous opening could not by any means be closed. In the course of a few months signs of cancer developed. The tumour mass was scraped, a catheter *a demeure* was inserted, the bladder washed out regularly, and in this way the man's existence was rendered tolerable to the end. The tumour itself, however, steadily continued to grow. Examination of the scraping showed flattened epithelium, so the growth was a canceroid.

Prognosis in such cases depended on the time at which the affection was recognised and on the site of the tumour. It could originate in the epidermis of the skin and spread internally or *vice versa*, as Posner had shown cylinder epithelium could be converted into parchment epithelium and harden. In advanced cases the structure of a new growth would not of a certainty prove its origin.

Deafness and Hearing Exercises.

Hr. Treitel said that Urbanstschitsch, of Vienna, who introduced the practice of hearing or listening exercises, believed that the hearing power was improved by them. He himself thought not, but only that the deaf children learned to combine. Listening to the tones of tuning-forks was of no practical use.

Congenital deafness, as distinguished from acquired, was frequently associated with mental weakness. This point was very important. For, with children with sufficient hearing power and sufficient intelligence, something could be attained by hearing exercises. It was more difficult with children who had only vocal hearing. It was questionable whether in the case of the totally deaf such attempts should be made, or whether as many teachers were of opinion the attention should be diverted from lip reading. It would be more correct to institute different classes, in which the totally deaf should be instructed quite apart from the others, as was already the case in some foreign countries.

Austria.

[From our own Correspondent.]

Vienna, December 20th, 1902.

Sporadic and Endemic Cretinism.

Kassowitz continued the discussion on Pineles' paper before the Gesellschaft der Aerzte. He considered Pineles' nomenclature at fault, as "congenital myxœdema" and "infantile myxœdema" were not good definitions. He thought "congenital" and "acquired" would be better, although he had some doubt about the acquired form, as out of twenty-three cases which he had carefully examined he found that the myxœdema was in all congenital. Again, the opinions of different observers varied so much that it was difficult to determine if the disease was transmissible from one to another at all.

Judging from the photographs produced by Pineles the congenital form which he described was not so severe as he would have us believe, as many of the severe symptoms were quite absent, such as the idiotic or other complicated signs. The *formes frustres* of Pineles was nothing more than an abortive form of myxœdema.

Kassowitz thinks that there are other two morbid conditions that should be viewed as derived from the same origin, viz., micromelia and Mongolism. All the three had a sunken glabella, from the early synostosis in the pterygoid, as well as the epicanthus which was common to all. In addition to these common traits there are a few malformations constantly present, viz., umbilical hernia, deformed aural appendages, inguinal hernia, cryptorchidism, non-union of the fontanelles, &c., &c. It is true that Virchow, at an earlier period of our history, gave it as his opinion that micromelia was a form of rhachitis fœtalis, which has since been proved to be an error, as the large joints and flexible bones are absent. It must be admitted that the etiology of all the three diseases is very obscure, and that the thyroid plays a very active part in all the three, although the complex symptoms raise doubts of all being genuine myxœdema; more probably micromelia and Mongolism depend on a morbid condition of some other gland or glands than the thyroid, which would isolate myxœdema, micromelia, and Mongolism.

Before this problem can be solved, a large amount of careful observation must be collected and facts collated in obstetric practice to support the hypothesis.

Rosenberg agreed with Kassowitz that rudimentary cases of cretinism were not due to the agency of the thyroid. He now recorded the history of two cases in his own practice which came into the world perfectly normal, fed on the breast up to the ninth week, when a prepared food was given in the third month. Immediately after this change all the complex symptoms of myxœdema set in. Kassowitz's statistics of twenty-two cases, having only two in the early part of the first year of life that were suspicious myxœdema, appear to be correct. It is not to be assumed that this proves perfection of the thyroid at birth, when the child continues healthy till weaned, and thereafter suddenly develops all the symptoms of myxœdema. The hypothesis is that the mother's milk supplied all the wants of the thyroid, but as soon as this natural diet is withheld the symptoms of struma priva appear at once, thus proving that an agency is conveyed through the mother's milk that supplies the absence of the gland. This is abundantly proved by Bramwell's experiments, who fed two children of undoubted struma priva by two nurses who were treated with thyroid gland.

Paltauf cannot agree with Kassowitz that myxœdema, micromelia, and Mongolism have the same origin. The anatomical pathology of micromelia is a chondro dystrophia, which has really no connection with myxœdema or the thyroid gland. A real dwarf has all the cartilages in perfection. Mongolism, according to Kassowitz's own showing, has no connection with the thyroid, and may therefore be dismissed from the category at once. The common symptom he referred to of the synostosis of the spheno-occipitalis cannot be accepted as proving a common etiology, although it must be admitted as a coincidence in the three morbid conditions. Biedl's experiments with different animals do not relieve our difficulty. He found that dogs and cats deprived of the thyroid became simply dwarfish with no intellectual defect, while goats and lambs, on the other hand, treated in a similar manner were stupid and idiotic.

Kassowitz said he objected to the term "cretinoid" if no cretinoid connection existed, but he was inclined to believe that some relation existed which to his mind was proved in the treatment of micromelia and Mongolism with thyroid gland. The great resemblance of the symptoms was to his mind conclusive proof.

Knopfelmacher said that in his long series of cases at the Children's Hospital, where there was perfect absence of the thyroid, it was in the second half of the first year of life that myxœdema presented itself in all its force, and more particularly in the assimilation of sugar stuffs which appear in the urine to the extent of 160 grs., but after a few days' treatment with the thyroid the amount will fall to 75 grs. or less.

On the other hand, however, he never got satisfactory results when the same treatment was applied for Mongolism, and therefore concluded that Mongolism was not intimately associated with myxœdema.

Offer said that Porge's experiments showed that cane sugar was converted into levulose when a struma priva was treated with the gland.

Weiss said that he had carefully watched 350 new-born children and found two with Mongolism but none with myxœdema, which, when treated with thyroid, had a negative result.

Pineles, in conclusion, defended "infantile myxœdema," which he considered was acquired. The children came into the world quite healthy, and would continue growing in perfect proportion for a year or so, and then suddenly, without any obvious cause, take on a struma priva condition.

The Operating Theatres.

ST. PETER'S HOSPITAL.

Hydatid Cyst of Pelvis Simulating Distended Bladder.—Mr. **Swinford Edwards** operated on a man, æt. 36, who had been admitted with the following history:—He had suffered five months ago from retention of urine which was relieved by catheterisation; a month afterwards he had another attack, and again another a week from the time of the present operation. He had increased frequency of micturition; by day nine or ten times, and at night once or twice; he had never suffered from hæmaturia, nor had he had any stricture. On examination *per rectum* there was a large, hard mass at the situation of the trigone. Mr. Edwards said he had endeavoured to examine the bladder by means of the cystoscope a few days previously, but, although he could pass a full-sized catheter into the bladder, he was not able to introduce the cystoscope. There was a large swelling externally, extending from the pubes up to the umbilicus, and this, when examined bimanually, that is to say, with the finger of one hand in the rectum and the other hand over the abdomen, gave the impression of being a large, tense cyst; and a distinct thrill could be elicited. Mr. Edwards also mentioned that, on passing a catheter, and evacuating all the urine possible, no difference could be detected in the abdominal swelling. A suprapubic incision was made, and on opening the pre-vesical space the bladder wall was clearly seen lying in front of the cyst. As the cyst appeared more prominent to the left of the middle line, the bladder was dissected free and pulled over to the right side. The cyst was now exposed, having peritoneum above it and collapsed bladder to the right. An incision having been made into the cyst, from a pint and a half to two pints of clear watery fluid escaped, and one or two daughter cysts presented. Mr. Edwards now shelled out the lining membrane of the cyst, which came out *en masse*, containing in its outer or fibrous wall two or three secondary cysts. The cavity remaining was thoroughly mopped out with gauze swabs, the opening in it stitched to the margins of the skin wound, and a large rubber drain inserted. Mr. Edwards said that this was a rare form of disease in this locality; he thought that the cyst had sprung from between the rectum and bladder, and was bounded above by the recto-vesical pouch of peritoneum; as it increased it gradually raised the peritoneum and pressed on the bladder, giving rise to increased frequency of micturition, and latterly to two or three distinct attacks of retention. He pointed out that no difficulty in defæcation had been complained of, although the lumen of the rectum was distinctly impinged upon. The case, he said, had been sent to the hospital as a case of distended bladder, due to a stricture or to some prostatic trouble, nor was the true nature of the case discovered until the patient was under the influence of an anæsthetic. He pointed out how readily in this case the bladder itself might have been damaged in incising the cyst; if this had occurred the prognosis would not have been a good one; this accident was avoided by throwing a good light into the wound, thus causing the muscular coat of the bladder to be distinctly seen. The peritoneum, he remarked, although raised by the cyst itself, was carefully kept out of the way. Why this man should have suffered in this way was, he thought, a difficult point to elucidate, as there was no complete history beyond the fact that the patient was fond of watercress, in which he indulged from time to time.

The case, a fortnight after operation, was doing well; all bladder symptoms had disappeared.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 24, 1902.

OYSTERS AND TYPHOID FEVER.

Some years ago it was ascertained that the poison of enteric fever could be conveyed to man by the agency of contaminated oysters. The public was straightway seized with consternation, and the oyster trade received a well-nigh fatal blow, from which it has since recovered only in a slow and partial manner, and this valuable article of food has fallen to a comparatively reasonable price. Hardly, however, has the popular distrust faded away sufficiently to inspire fresh confidence among consumers than there comes news of fresh disaster which will infallibly sound the death-knell of the trade concerned for many a year to come. The facts of the case may be briefly stated as follows:—At the beginning of last week typhoid fever was reported from several towns on the Southern coast, notably Portsmouth and Southampton. After a few days the occurrence of the malady in epidemic form was definitely announced, and Winchester was added to the list of towns involved. Almost simultaneously the disease was traced to oysters obtained from Emsworth, a small town on the South Coast, where the oyster beds are systematically exposed to gross sewage contamination. On November 11th last, a Mayoral banquet was given at Southampton, an occasion which naturally brought together a number of official visitors from neighbouring towns. The consequences have been widespread disaster, as the disease has been distributed broadcast by the consumption of Emsworth oysters at Southampton. In Portsmouth, for instance, at least fourteen cases were traced to the ill-fated civic feast, and the local medical officer of health feared that further cases would yet be notified. In Southampton itself several public men and corporation officials have been attacked. The worst results up to date have followed at Winchester, in which town a leading medical man, Dr. William England, has succumbed to the disease. Another victim was a waiter named Small, who lived at Winchester but was engaged at the Mayoral banquet. The Dean of Winchester, another of the guests, appears to be happily escaping from the grasp of this most perilous yet most preventible of infectious diseases. At Emsworth, the ultimate centre of all this holocaust of suffering and death, thirteen cases of enteric fever are said to exist at the present moment, a fact that abundantly explains the specific contamination of the oyster beds which are so elaborately inundated with the sewage of that primitive municipality. Oysters from Emsworth have doubtless been eaten with impunity so long as the sewage of the town was free from the germs of typhoid fever and of other pathogenic bowel organisms. The advent of an enteric fever patient at Emsworth, however, has laid spark to the gunpowder. The question that will occur first of all to sanitarians is, why the powder magazine was not cleared out long ago, so that any lighted match would be rendered harmless. In other words, dropping simile, why was Emsworth allowed to keep oyster beds at its own sweet will under filthy, revolting, and dangerous conditions? The facts of oyster-borne typhoid have been long before the world, and the special relations of the oyster fisheries, and storage and culture beds to the disease have formed the subject of an elaborate report presented by the Medical Officer of the Local Government Board. How then does it happen that years later the oysters from a notoriously polluted source are permitted to poison persons wholesale? It is customary for the inhabitants of the United Kingdom to plume themselves upon the progressive nature of preventive medicine. In the particular case of oyster-typhoid, however, there is clearly little room for self-congratulation, for no effectual steps have been taken to rob the situation of dangers that have been ascertained some half a dozen years ago with laborious accuracy. Read in this light, the resolution of the Southampton Town Council certainly does not err on the side of hot anger and reproachfulness. "That in view of the serious infection," it runs, "incurred from the eating of shellfish infected with sewage, it be recommended to the Board of Trade that in all cases where there exists an organised system of drainage from urban or rural sanitary districts, the crude sewage shall be efficiently treated by some septic or other process before discharging into the sea or stream under the control of the Sea Fisheries Committee, and to request the Local Government Board to consider and take such action as they may deem necessary." Among pressing domestic reforms that of the sanitary control of the shellfish trade stands well in the front. When a little attention can be spared by the Legislature from the four corners of the earth to the reforms needed at our own doors, then, and then only, will the population of the United Kingdom be likely to get rid of the pestilence that is bred in sewage-polluted oyster beds. Now that a score of corporation officials and a dean of the Established Church have been attacked by typhoid fever, as it were *coram publico*, we may perhaps hope for decisive Government action.

EARL DUDLEY AND THE MEDICAL PROFESSION.

THE opening of the Nurses' Home and new operating theatre at the Adelaide Hospital in Dublin the other day afforded His Excellency the Lord Lieutenant an opportunity of testifying his gratitude to the medical men who have attended on the Countess of Dudley during her late illness, and through them to the medical profession at large. His Excellency has during his stay in Ireland improved on each opportunity that he has had in making himself more popular with Irishmen of every class, and his words on that occasion will go far to increase that popularity with the members of the medical profession. "I, personally, am never likely to forget the deep debt of gratitude that I owe to the surgeons and doctors who have so skilfully watched over the course of Lady Dudley's illness; and, naturally enough, if, during the rest of my stay in Ireland, I am able in any way that I can to show my gratitude in connection with hospitals, or in any other way with your profession in this town, an appeal will never be made in vain." These are straightforward and striking words, and when they are let fall by a man of Lord Dudley's personality they augur that at least the medical profession has a powerful and steadfast friend. The opportunities which are now, and will in the future, be afforded to such a friend of proving his desire to help are many, but, unfortunately, where his Excellency's help is most needed, he will be so invested by the coils of red-tape and of officialdom that he will be a strong man indeed if he succeeds in breaking free. Was it but possible for him to break through these coils, and to use his power as he would himself wish to use it, the opportunity is before him. Could he but effect some of the many needed reforms in the Irish Poor-law Medical Service, when his time came to return to England he could leave Ireland confident that, whatever else he had done, he had assisted to convert a present bondage into a valuable Service, that he had benefited those to whose wants that Service ministers, and that he had more than discharged any small debt which might have been laid upon him by the medical profession through the successful efforts of a few members of it. Even if it is at present impossible, in the nature of things, that Lord Dudley could—no matter how he desired to do so—effect any reforms in the Poor-law Service, he might on his return to England constitute himself a powerful friend were he but familiar with the facts. One of the last acts of Her Excellency, before she was attacked by her serious illness, was to testify to the courage and nobility of character of a member of the Poor-law Medical Service—the late Dr. William Smyth. That gallant gentleman was honoured in his death, but how is many a similar man dishonoured in his life. A few words will tell. He is expected to work early and late for a salary that a mechanic would refuse. If he is ill, or is overworked he must pay for the substitute who does his work while he is absent. If he becomes permanently incapacitated, even by a long life's work spent in the service, he must in many cases retire to want, or he must continue the task for which he is physically incapacitated and die in harness as an alternative to the workhouse. These are the old grievances of the Service which are always present, but, so far from their removal. others are added. If a medical man is summoned to give evidence in a court of law he must pay for a locum tenens in his absence and thus often have to be a loser for the privilege of being of use to his fellows. If a medical man is summoned by the agent of the Poor-Law authorities to help a brother professional in a difficult case, he must either incur the odium which would attach itself to him if he refused to go or he must accept an absurd fee which has been fixed by those whose interests it is to diminish expenses. In other words once a medical man has entered the Poor-law Medical Service he must consent not alone to spend his life at an incessant and badly-paid task, but he must also consent to be turned into the means by which those in authority over him dispense a vicarious charity. And yet the reform of the Service would not be a difficult matter; a little less regard for the pockets of the ratepayers and for the Imperial Treasury, a little less fondness for a cheap reputation for charity gained by the efforts of other people, a little less desire to exploit one profession for the public benefit, and the public would reap the benefits that would accrue from a well-ordered and properly-managed Poor-law Medical Service, and they would be entitled to reap them. Would His Excellency but make himself familiar, not with the official account of the Poor-law Medical Service, but with the service as it really is in many country districts, he would not have long to look for a means of testifying his gratitude. The medical profession will always owe Lord Dudley a debt for the desire to help, but could he impress the points to which we have alluded on the controllers of the destinies of the Poor-law Medical Service, it would owe him a deeper debt for the help itself.

PATHOLOGICAL EVIDENCE AT INQUESTS.

THE not unnatural curiosity which we, in common with our medical contemporaries, have expressed concerning the sudden appearance of Dr. Freyberger as the official pathologist for the metropolis has been gratified in part by the statement of the chairman of the Public Control Committee at a recent meeting of the London County Council, "relative to the employment of a pathologist in making post-mortem examinations in inquest cases." Dr. Freyberger, it seems, was appointed conformably to a recommendation made by that committee and approved by the Council instructing coroners that, in the opinion of the Council, it was desirable that post-mortem examinations in inquest cases of a special nature should be entrusted to a specially skilled pathologist. To this proposition no exception can be taken, indeed it has always been the custom to employ a specially skilled pathologist in cases which from their nature, appeared to render such assistance necessary. The innovation consists in the appointment of a particular person, not by any means the best-known or most eminent in pathology, to carry out these examinations, to the exclusion of the many distinguished pathologists of the metropolis. We are informed that the Public Control Committee had previously arranged with Dr. Freyberger to make analyses in suspected poisoning cases, and "finding that he was an experienced pathologist" who, moreover, was prepared to make the examinations and give evidence for two guineas, they recommended his employment by coroners whenever special skill was required. It is not intended, we are told, that the medical attendant on the deceased should be superseded, and as Dr. Freyberger was only called upon in 34 out of 249 inquests it is suggested that such has not been the case. Incidentally we learn that Dr. Freyberger was wrong in describing himself as "pathologist to the London County Council," and will in future not so describe himself. The fact, however, remains that an innovation which, in the abstract, has much to recommend it, has been made in a hole-and-corner manner which contrasts unfavourably with the practice of public bodies in such matters. We should like to know in virtue of what occult influence Dr. Freyberger has been pitchforked into a post which, if thrown open to competition, would doubtless have attracted an adequate number of candidates with qualifications and experience possibly surpassing those of the committee's nominee. The matter is one in which medical men, as guardians of the public health and as expert witnesses in medico-legal cases, are naturally greatly interested, and had the committee proceeded in a less objectionable manner they would probably have secured the support of the profession in their praiseworthy endeavour to render coroner's inquiries more efficient than is at present the case. We do not care to insist upon the curious fact that it should have been found necessary to requisition the services of a foreign graduate to the exclusion of the many eminent pathologists whose names, or some of them, are household words among medical men, but the selection, if selection it can be called conveys an unmerited slur on native talent which is obviously uncalled for and in other respects objectionable. It is highly desirable that the matter should be thoroughly threshed out, because the explanation given by the chairman of the committee places the appointment in an even more dubious light, and we are convinced that the transaction will not secure that measure of public opinion in its support at which public bodies must, or should, always aim.

Notes on Current Topics.

Tube Railway Ventilation.

Before any more deep level railways are authorised it is to be hoped that some assurance will be obtained of the provision of more efficient ventilation than has so far been found practicable on the lines already in existence. For some reason the Central London Railway has proved specially faulty in this respect, and the analyses to which publicity has been given by the *Daily Mail* only confirm those previously made by independent authorities. It is hardly necessary to point out that when carbonic acid gas is taken as the measure of organic contamination, its presence in excessive proportions is of immensely greater significance than when, as in the atmosphere of London, it is largely due to the escape of the products of combustion. In view of this fact the presence of from ten to twenty parts of carbonic acid in the air of the tunnel, and especially in the carriages, is a matter of the highest importance. To remedy the existing state of things will tax the resources of engineers to the utmost. No measure which merely provides for a daily change of air will be satisfactory; for the tube to become even moderately healthy the ventilation must be constant and effectual, and, so far, no means have been suggested to secure either constancy or efficiency at times when the traffic is heaviest. We hesitate to affirm that the problem is likely to prove insoluble; but until it has been solved it behoves our legislators to hold their hands in the matter of authorising further tube construction.

Gangrenous Appendicitis.

Our Transatlantic *confrères* have, with characteristic conciseness of expression, applied the term "green groin" to the physical condition which develops when a violent attack of appendicitis passes on to gangrene of that so frequently troublesome organ. From the proximity to the surface the decomposition —especially in spare subjects—rapidly comes to engage the subcutaneous tissue and skin, thereby producing the characteristic discoloration. And in a recent contribution to this subject, which appeared in the pages of the *New York Medical Record*, Mr. Joseph Price expresses the opinion that such cases would be more truly described as "gangrenous appendix" than as appendicitis. The appendix when exposed is found to be in a state of sphacelus, with one or more perforations, and free leakage. The pocket of the right groin above Poupart's ligament is found to contain a large quantity of lemon-coloured septic fluid; and there are extensive omental and intestinal adhesions. There occasionally coexists a "Derby-hat" form of abdomen, within which the entire peritoneal cavity will be found filled with extravasated bowel contents, lymph, and other inflammatory products. The symptoms have sometimes closely simulated those of typhoid fever, and require keen discriminating skill for differential diagnosis. The fact that a considerable number of even such virulent cases recover after reaching this stage gives hopeful testimony towards the general prognosis of appendicitis.

Deaths Under Anæsthetics.

The large number of deaths occurring from the use or misuse of anæsthetics during recent weeks has caused considerable alarm among many of the newspaper-reading public. No doubt it is most desirable that every death occurring under such circumstances should be subjected to impartial and public investigation, but we venture to think that to a great extent, and all unwittingly, not a few coroners and journalists have recently done much to hamper medical science and needlessly alarm many nervous members of the community. Considering the enormous use made of general anæsthetics, the proportional mortality was probably never so low as it is at the present time. At no former time was greater care exercised in the preparation of the anæsthetic, the education of the anæsthetist, and the protection of the patient; and although we would gladly see still greater advancement made in the proper training of all medical men in the administration of such powerful agents as chloroform and ether, yet we strongly deprecate improvement by panic. We trust the discussion of medico-legal matters at the meetings of the recently-formed Medico-Legal Society will do much to encourage coroners in viewing such a matter as we have now referred to in its medical and scientific aspects as well as from the judicial and public point of view.

Infantile Prostatic Sarcoma.

Since Home's great monograph every student of medicine recognises that hypertrophy of the glandular tissue of the prostatic gland is the most common of its abnormalities. This hypertrophy is essentially a senile condition, and is simulated by pathological conditions occurring in early life. M. Potesco has placed on record a very interesting case of this nature. A child, one year and nine months old, came under his care in February of this year; it suffered pain on passing water and was constipated. There was a suprapubic swelling, and a rectal examination detected an enlarged prostate. The bladder was opened through the abdomen, and a sarcoma the size of a closed fist found. It has its origin from the prostatic portion of the urethra. Surrounding the urethral opening there was a thick ring of small polypoid tumours. Sarcoma, though more common in the human prostate, is a very unusual disease of the gland, and particularly so in such a young subject. The case is, moreover, interesting from a clinical point of view, as showing the necessity for a thorough examination in all cases of children complaining of bladder troubles. The case at no time offered any hope of success, though life might have been prolonged by inserting the ureters into the rectum and excising the sarcoma.

The State and the Climate.

Although the most pugnacious member of the Opposition can hardly accuse "the Government" of being responsible for the condition of the British climate, there is a sense in which the State may well play a part in facilitating measures for the improvement of, say, London's atmosphere, or, at least, securing sounder knowledge of meteorological conditions. We are glad to see that Mr. Balfour is not unmindful of this duty, and in order to inquire into the administration of the Meteorological Council and the means by which the interests of meteorological science may be furthered, the following Committee has been appointed:—Sir Herbert E. Maxwell, M.P. (chairman), Mr. J. Dewar, M.P., Sir W. de W. Abney, Sir F. Hopwood (Board of Trade), Sir T. H. Elliot (Board of Agriculture), Mr. R. T. Glazebrook, Mr. T. T. Heath (Treasury), and Mr. Joseph Larmor, F.R.S. Mr. G. L. Bristow, of the Treasury, will act as secretary of the Committee. We could have wished that medical climatology had received more prominent recognition on this Committee, for, after all, meteorology is perhaps mainly of importance in so far as it influences, directly or indirectly, the health of the people.

Gall-Stones.

The time when operative treatment is called for in cases of hepatic colic from the passing of gall-stones must rest on the conditions of each individual case; but early surgical intervention is, as a rule, to be recommended unless the case presents some feature that prohibits operation. A case recorded by Signor Braquehnye at the recent French Congress of Surgery strengthens this view. A patient, who suffered from the jaundice of obstruction, and who from to time passed gall-stones in his stools, finally recovered, but afterwards was attacked by severe pains in the region of the gall-bladder. A laparotomy revealed an empty gall-bladder with adhesions to all the neighbouring viscera. Now, it is reasonable to suppose that an early operation would have obviated this risk of localised peritonitis, which, from the many adhesions of the viscus, appear to have followed on the passing of each gall-stone. The question to be answered is: What gives the best immediate results and what the best after-results? The patient naturally shrinks from operation and prefers the olive oil, laudanum, or chloroform, or, at least, is anxious such medication should have a trial, and it requires some moral courage to recommend an operation, but in view of the better after-results and for the relief to the patient's mind that there are no more calculi to be passed, we think operative treatment is, as a rule, the preferable procedure.

Alcohol and Research Work.

Although alcohol is sadly abused by an all too-numerous section of the community, and restraint is necessary in limiting the evil as far as possible, yet it must be remembered that alcohol is a very important and necessary agent in research work. A number of scientists, acting in accordance with instructions received at the Glasgow meeting of the British Association, have approached the Board of Inland Revenue with a view to obtain relief from the heavy taxation on pure alcohol used in scientific laboratories and where higher teaching and research are carried on. Regulations have now been issued whereby ethyl and methyl alcohol may now be supplied to duly recognised places and under special restrictions, so that another of the fetters limiting scientific research in this country has been loosened. But we trust that those scientific institutions availing themselves of this relief will rigorously ensure the use of this alcohol for legitimate purposes, and stringently protect those who may in any way be tempted to lapse into irregular forms of inebriety.

An Unusual Sequel of Ovariotomy.

The removal of both ovaries, as is well known, is often followed by unpleasant results, but M. Bovey's two cases of intense pruritus following double ovariotomy are too unusual to pass unnoticed. The cases occurred at an interval of years, and in both the itching was so intense that the patients lacerated their skin by constant scratching. All the ordinary remedies — buttering, ointments, lotions, and such like—failed to give relief until fresh ovaries of the calf were tried in 1·50 grain doses daily. What the relationship is between the ovary and the sensory cutaneous nerves we know not, but that there is some correlation the cases go a long way to show.

Surgery of the Hip-Joint.

When in 1869 M Ollier first recommended operative interference with the hip-joint for tuberculous disease of the femur, his suggestion was so much in advance of the surgery of the day that it did not meet with general approval. A deep wound through vascular tissues meant in the sixties profuse suppuration, "laudable pus," hectic fever, and too frequently death. Aseptic conditions, have, however, changed all this, and not only has M. Ollier's operation been adopted, but his principles of surgery have been applied to other pathological conditions of the joint. M. Janesco, of Bucharest, has in cases of old-standing femoral dislocation, where the ordinary methods adopted for the replacement of the head of the bone have not been successful, cut down on the joint and excised the head of the femur, and approximated the apex of the great trochanter to the cotyloid cavity. He makes provision for drainage by trephining the trochanter, and through this channel he passes gauze into the floor of the cavity. The operation is not a new one; in a few exceptional cases it has been done in the past. But to M. Janesco should be given the credit of demonstrating its safety and advocating its adoption as the accepted treatment in old-standing femoral luxations.

The Ventilation of Factories.

A new era in the scientific ventilation of factories bids fair to be inaugurated under the guiding hand of the Departmental Committee appointed to inquire into the question. The first report of that body has appeared in the shape of a blue-book, with appendices. The great principle is recognised that the ordinary standard of cubic space per head affords no reasonable guarantee of proper ventilation. It is proposed to substitute the more trustworthy test of chemical analysis, whereby the amount of carbonic acid vitiation can be accurately determined. It is consequently recommended that, under the powers conferred by the Factory Act, 1901, a standard of ventilation be prescribed for all classes of factories and workshops, so that the proportion of carbonic acid in the air at the breathing level shall not, except on foggy days, rise beyond twelve volumes of carbonic acid per 10,000 of air. When gas or oil is used for illuminant purposes the proportion shall not exceed twenty volumes after dark or before the first hour after daylight. Due allowance is further made for extra carbonic acid resulting from trade processes, as in breweries. It is also recommended that notice of the result of analyses be communicated to employers, and that a reasonable time be allowed to permit alterations, which will be followed by further air tests. Arrangements are suggested for the purpose of engaging the services of a specially qualified person to conduct the analyses for the Factory Department of the Home Office, and for the appointment of inspectors, if desired, who will be able to test the air on the spot by means of a suitable apparatus.

Nurses and Plague Work.

The return of the nurses who for the last three years have been on plague duty in India has been at length officially notified. Our contemporary *Truth*, in drawing attention to that fact, suggests that a special recognition should be made of the particularly arduous and repulsive work done by these devoted women. In many ways their service has been more dangerous and exacting than that undertaken by Army nurses in South Africa and China, for which numerous medals have been awarded. Several nurses have died of plague, and in our opinion have thereby earned a right to the highest distinction which can be bestowed upon the memory of any member of the community who has sacrificed his or her life for the good of mankind. The Victoria Cross is justly earned by a brave soldier by facing the foe or by rescuing a wounded comrade. His momentary valour, however good and commendable though it be, weighs light in the balance compared with the calm and sustained courage of the nurse who tends plague-stricken natives month after month and year after year, away from the excitement of war and conflict. Nothing need be said about the fact that the saving of life is obviously a higher motive than its mere brutal destruction, inasmuch as the soldier acts under orders, and war is unhappily only too often a necessary evil in the present imperfectly developed stage of the world's morality.

The Imperial Vaccination League.

The Imperial Vaccination League, under the presidency of the Duke of Northumberland, has now entered upon the active stage of its existence, the first meeting having taken place a few days ago. We may remind our readers that the object of the League is to place more clearly before the public the immense value of vaccination and revaccination, and to study the operation of the Vaccination Act of 1898 in the hope of being able to formulate improvements which will tend to diminish opposition. With this object in view, certain special questions are being investigated by committees of experts, such, for instance, as to the desirability and possibility of compulsory revaccination before the legal age for employment, the transference of the administration of the Acts from the Guardians to some other body, the supply of lymph, and to define a standard of "efficient" vaccination. The chairman pointed out that some, at any rate, of the difficulties which had been met with were probably due to a failure to appreciate the importance of certain objections, although most of these had been obviated by the employment of glycerinated lymph. He spoke hesitatingly on the question of compulsion, and deplored sundry features of recent legislation. The Bishop of Stepney urged that they of the League should not only endeavour to spread the truth, but also to remove the causes by which the truth about vaccination had been misunderstood. An executive committee was elected, and arrangements made to carry on the work. In view of the imminence of fresh legislation on the subject there is evidently no time to be lost. The League may rely upon the cordial support of the medical profession, and we trust also that of the educated classes of the community.

Cockles and Typhoid Fever.

At the present moment, when the public attention has been so forcibly directed to the question of shellfish-typhoid, the recent report of the Medical Officer of Shoreditch has a peculiar appropriateness. The oysters which played so disastrous a part at the Southampton civic banquet in spreading enteric fever through various neighbouring towns, gives way to the cockle in Dr. L. F. Bryett's interesting and valuable remarks on the typhoid outbreaks that raged in the East End of London last July and September. He attributes the epidemic solely to the sufferers having consumed cockles while holiday-making at Southend-on-Sea. The cockles were from beds situated in the Leigh Creek, about a quarter of a mile below the outfall of the Leigh Sewage Works. It has been shown that the Bacillus typhosus is capable of surviving in the interior of a cockle that has actually been subjected to the process of boiling. This disquieting information should make the Local Government Board more than ever alive to the necessity of adopting or securing drastic measures of control over shellfish beds and ponds. Curiously enough, the information in question was furnished to the Board by one of their own investigators, and they have been fully informed by special inquiry as to the environment of every important oyster and shellfish bed in the United Kingdom. Among others the filthy pollution by sewage of the Leigh beds was fully exposed. Does the Board think that their responsibility ceases now that the public is authoritatively informed of the magnitude and exact location of the danger?

Small-pox in the Provinces.

The London outbreak of small-pox appears to have exhausted its violence, although it would be premature to assume there will be no further access of epidemic activity. Signs are not wanting, however, to show that the vast amount of infective material recently engendered in the metropolis will act as a centre of ever widening circles of infection throughout the United Kingdom. During the past twelve months that fact has been abundantly illustrated again and again in England, Scotland, Ireland, and Wales. At the present moment tramps are carrying the disease about the country with their usual well-recognised certainty and impartiality of distribution. Their wanderings to and fro over the face of the land appear meanwhile to be regarded by many of our local governors with a spirit of fatalism that an Oriental despot might envy. It would be far more practical to apply quarantine to tramps or to secure their control in other ways than to build hospitals, and to prepare to give the enemy a warm reception. A significant note of alarm has recently been uttered at Salford, where the Corporation have issued a notice asking the public not to attend football matches for the present, except in Manchester and Salford. The reason given for this request is that small-pox is prevalent in neighbouring towns in Lancashire and Yorkshire. It would be interesting to know whether the Salford authorities have displayed a prudence with regard to tramps equal to that which has dictated their football policy.

The Standardisation of Drugs.

The more one considers the question of the standardisation of drugs, to which attention was first called by Mr. Moore in his recent work entitled "Suggestions for the Standardisation of Purity in Drugs," the greater is the importance it assumes from the point of view of the prescriber. Mr. J. C. Umney's elaborate contribution to the discussion is based on a very comprehensive inquiry into the matter, and he makes several suggestions of practical value. It is easy enough to standardise a preparation of a drug which owes its activity to a particular alkaloid; but, after all, the simplest plan in such case would be to employ the alkaloid itself. But there are others which act in virtue of a mixture of alkaloids, and for these the only method must be the estimation of the tota alkaloids, although this leaves their relative proportion open to variation. Then, too, there are drugs which do not owe their activity to alkaloids or active principles of which we know enough to allow of accurate estimation, and there is a further class which can only be measured by the amount of extractive, such as aloes, cascarilla, &c. Mr. Umney urges the official recognition of "average standards," of which he has taken the trouble to draw up a long list. These would be penal standards when adopted, and then, at any rate, we should have something to go by.

A New Railway Risk.

The prospect of being able to travel by rail at the rate of a hundred miles an hour or so, by the substitution of automobile carriages for the ordinary heavy locomotive and train, is an enticing one to those whose nervous systems do not shrink from such rapid motion, especially as less vibration is likely to be experienced than is the case with the heavy and comparatively slow trains of the present *regime.* There is one detail, however, which goes far to extinguish the enthusiasm felt at first sight. Each automobile railway carriage, it seems, will carry a supply of highly inflammable liquid fuel varying, according to the distance to be traversed, from thirty to eighty gallons. Now our railway managers have themselves recognised the dangerous nature of this fluid by imposing the most irksome restrictions on its transport over their lines and although, if the automobile system be adopted—and an announcement to that effect in regard to one line has already been made—proper precautions will doubtless be taken to prevent the possibility of leakage and consequent explosion or fire. One shudders to think of the inevitable result should an automobile train leave the rails or sustain anything of the nature of a collision. To the usual, and already serious, risks to which passengers are exposed in the event of a railway catastrophe will be superadded the quasi-certainty of an instantaneous and gigantic conflagration involving the whole of the wreck. The only set-off to this contingency is that the passage of the petroleum vapour into the lungs would probably determine insensibility forthwith, partly by asphyxia and partly in virtue of its poisonous effect on the blood. However regarded the prospect is an unlovely one; for the margin of safety which exists in regard to possible mangling or other form of physical deterioration appears likely to be sacrificed altogether should the craze for ultra-express trains lead to this system being adopted.

Sleeping Sickness.

This remarkable disease, the pathology of which is still obscure, has hitherto been regarded more or less as of the nature of a curiosity; but Dr. Low's report brings home to us the fact that it exists in a highly epidemic form, having already caused the death of 70,000 natives in Uganda, some 15,000 more actually suffering therefrom. The disease is practically always fatal, so that the increased virulence with which it is credited must bear on its rate of spreading rather than its gravity. The natives are terrified, and move from one area to another *en masse*, so that large tracts of country are rendered desert. No doubt is entertained of the bacterial origin of the malady, and there is reason to hope that the specific germ may shortly be identified, but between its identification to the stamping out of the disease there is a wide gap. The symptoms and pathological changes point to the existence of a peculiar form of meningitis which, like most other forms of meningitis, is absolutely refractory to treatment.

Medical Men and Out-Patient Departments.

At Leigh, near Manchester, an infirmary is about to be erected on a site given by Lord Lilford, and the Town Council have decided to have an out-patient department and dispensary in connection therewith. The local practitioners have entered a formal protest against this addition to the original scheme, and refuse to provide an honorary medical staff unless their services be restricted to in-patients. The Committee of Management will therefore endeavour to carry on the work with the assistance of two or more resident house surgeons—it remains to be seen with what success. This opens up a question which before very long will come to the front in connection with hospitals everywhere. The abuse of medical charities from which the profession as a whole suffers so severely is mainly in the out-patient departments of hospitals, and much more stringent provisions than have hitherto been attempted will have to be made before any tangible improvement can be hoped for. If the out-patient department were limited to the sick poor suffering from diseases certified to call for special skill in diagnosis or treatment the abuse would cease, and medical men would gladly avail themselves of the department to assist them in difficult cases. The concerted action of the Keighley local practitioners is a sign of the times, and we trust is but the prelude to similar action on a larger scale.

Coroners and Fees to Hospital Medical Officers.

At an inquest held at Keighley last week the coroner referred to the recent rule which debarred him from paying a fee to medical men in connection with any case in which the patient had been taken to a district hospital. With commendable frankness he declared this restriction to be "a monstrous shame," and he called attention to the iniquity of depriving a practitioner of a well-earned fee merely on the ground that he gave his gratuitous services to a local hospital. The injustice of the rule is so obvious that we are surprised individual practitioners have not ere this taken steps to protest. There are several ways of protesting, and the first would be for every practitioner so aggrieved to bring his grievance before the proper authority. Should this course not be productive of reform, concerted measures will have to be taken to secure the removal of this flagrant injustice. Even in respect of medical hospital officers in receipt of a salary, always nominal in amount, we see no reason why they should be asked to give evidence for nothing. But to debar the honorary members of the staff from remuneration is so palpably unjust as to render further argument unnecessary.

Unqualified Practice.

The coroner for the Marylebone District last week investigated a case in which a young unmarried woman died under suspicious circumstances. At the post-mortem examination evidence was found pointing to the performance of an illegal operation, with subsequent blood-poisoning. Deceased had been attended by one Caleb Whiteford, formerly a member of the English College of Surgeons, but disqualified some years ago upon being sentenced to a term of penal servitude. This person is carrying on medical practice at a dispensary, in spite of the fact that his name has been erased from the *Register*. The law thus allows the General Medical Council to remove a practitioner's name from the list of persons qualified to practice, but does not empower that body to prevent his continuing unqualified practice. This absurd anomaly is taken advantage of by many disqualified persons, of whom notorious examples are at present to be found in the Metropolis in the cases of Allinson, Alabone, and Whiteford. It seems almost incredible that Whiteford, in the light of previous experience, should allow himself to be involved in another "West-End Mystery," as the newspapers describe the case. When giving evidence he stated he was prepared to give a certificate of death if necessary. It would be interesting to know how many of these illegal certificates have been accepted by local registrars and what the Marylebone coroner has to say upon the subject. In the case under investigation the jury returned an open verdict, but it is hardly to be supposed that the police will permit the matter to end there.

It is stated that Miss Glendenning, a trained nurse, has brought an action to recover damages to the extent of £1,500 for alleged breach of promise of marriage against Dr. John W. Byers, Professor of Obstetrics and Medicine, Queen's College, Belfast. The defence is based upon a denial of the alleged promise.

PERSONAL.

Lord Lister has been created by the King of Denmark a Knight Grand Cross of the Order of Dannebrog on the occasion of his jubilee.

Dr. Henry R. Oswald has been appointed by the London County Council Coroner of the south-eastern district at a salary of £943 10s. per annum.

Dr. Norman Moore has been elected Physician to St. Bartholomew's Hospital, and Mr. W. Bruce Clark Surgeon to that ancient institution.

Professor Francis Darwin, F.R.S., Sir Andrew Agnew, Bart., M.P., and Sir John Williams, Bart., M.D., have joined the Imperial Vaccination League as vice-presidents.

Dr. Nothnagel, Professor of Clinical Medicine and Therapeutics at the University of Vienna, has been nominated a life member of the Upper House of the Austrian Parliament.

Mr. G. G. Hamilton, M.B., F.R.C.S., has been appointed to the post of Honorary Surgeon to the Liverpool Royal Infirmary, rendered vacant by the resignation of Sir William Banks.

Dr. Poirier having been appointed Professor of Anatomy to the Paris Faculty of Medicine, a congratulatory dinner was offered him last week at which M. Waldeck-Rousseau took the chair.

A **special** reception is to be held by the Lord Mayor of Liverpool and the Lady Mayoress to congratulate Professor Ronald Ross, C.B., F.R.S., on his selection as the recipient of one of the Nobel prizes.

Special Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents.]

SCOTLAND.

[FROM OUR OWN CORRESPONDENT.]

The Principalship of Edinburgh University.—A meeting of the Curators of Patronage was held on the 16th inst. for the purpose of considering the vacancy caused by the retirement of Sir William Muir. All the curators were present except Treasurer Cranston, who was indisposed. No definite selection was made on this occasion, the curators resolving to adjourn until the 20th prox., when an appointment will probably be made. It is neither the practice to advertise such a vacancy nor otherwise to invite applications for the post. While several names have been suggested as possible, there is a very general belief that the post will be offered to Sir William Turner, the present Professor of Anatomy in the University, and President of the General Medical Council, whose strength of character and unrivalled knowledge of University business have for many years given him a high position in all the counsels of the University.

Bangour Asylum Scheme.—Allusion has already been made more than once in these columns to the very unsatisfactory state of matters into which this scheme has drifted. The Edinburgh District Lunacy Board had before them, on December 15th, a communication from the Lunacy Commissioners which seems to provide a simple and feasible solution of the present difficulty as to the accommodation of the insane poor, and which will also, in all probability, effect a considerable saving to the rates. The Lunacy Commissioners in effect insist, under the powers conferred by Act of Parliament, that the District Board take immediate steps to provide for their insane poor, and suggest that they should do so by erecting on the Bangour estate five wood and iron structures capable of accommodating forty patients each. The Commissioners sanctioned the erection of such structures at Woodilee Asylum, Glasgow, last June, and they are now in working order. Their cost, including electric light, water, heating, and furniture, works out at £125 a bed. The Commissioners are satisfied that, if properly constructed and attended to, these buildings will endure for a very long period, and have accordingly recognised them as part of the permanent structure of the Woodilee Asylum. Four of the proposed buildings are to be for patients, and the fifth for administrative purposes, while eventually all would be available for easily managed male patients, and would render unnecessary the erection of a corresponding number of villas. The recommendation of the Commissioners was approved by the Board, and it was accordingly arranged that the asylum committee should visit Woodilee with a view of erecting similar structures at Bangour forthwith.

Sanatoria for the Consumptive Insane.—Two sanatoria for this purpose were opened last week by the Glasgow Lunacy Board—one at Gartloch, the other at Woodilee. The type of construction used throughout is novel in such buildings. It is of a composite wood and iron character, on a system of air-spaced walls, patented by the designers of the building, Messrs. Spiers and Co., Glasgow. The interior covering is a peculiar papier-mâché composition, and presents a surface like plaster, absolutely non-porous and jointless, all angles and corners being rounded so as to allow of efficient disinfection. For the rest the buildings have ample air space, and the large ventilating windows, verandahs, &c., usual in sanatoria. Accommodation is provided in all for 162 patients, and the buildings were handed over to the Board ready for occupancy in the brief period of sixteen weeks from the commencement of the work. The cost is about one-third of a stone and lime erection.

Presentation to the University of Edinburgh of a Bust of Sir William Muir.—Some four or five years have elapsed since a movement was set on foot to have a bust of Sir William Muir executed that it might be placed with the memorials of distinguished principals and professors in the Library Hall of the University. The completion of the work was unavoidably delayed, and the bust was formally unveiled by Lord Kinross only a few days ago. Lord Kinross, in eulogising their late Principal, alluded specially to his friendship for the students, shown in a practical way by the interest he had taken in the erection of the Students' Union, and in the establishment of women's halls of residence, one of which bore his name. Sir William Turner, as the senior colleague of the Principal, accepted the bust on behalf of the University, and Sir William Muir, who was present at the ceremony, made a few remarks. The bust was considered an excellent likeness while it was exhibited at the Royal Scottish Academy; it is the work of Mr. Charles McBride.

Special Article.

THE MIDLAND MEDICAL UNION.

The annual meeting of the Midland Medical Union was held at the Hotel Portland, Chesterfield, on Thursday, December 4th, 1902, at 4.30 p.m., the President, J. Goodwin Shea, Esq., M.D., J.P., in the chair.

After the election of officers, reports, of which the following are summaries, were presented and adopted:—

During the past year the work of the Union has concerned the outlying districts more particularly than Nottingham. The branch at Nottingham has, therefore, little to add to the reports from Mansfield, Chesterfield, and Belper.

With regard to the executive, it should be stated that there have been six meetings of the Council, one of which was held at Chesterfield and the rest at Nottingham. The principal business transacted at such meetings was the consideration of the Teversal matters and of the Medical Aid Association at Chesterfield.

The appeal made under the authority of the Council to aid Dr. Rainsbury in defraying the judgment in the case of Webster *v.* Rainsbury met with a generous response. The total amount required was £182 6s. 2d., and the appeal has up to the present realised £71 15s. 9d., leaving a balance of £110 10s. 5d., which has been paid by Dr. Rainsbury.

During the past year the work of the Chesterfield branch has been devoted chiefly to dealing with the rate of remuneration paid by the Friendly Societies in this district. In the last annual report it was stated that a conference was to be held between representatives of the Union and the Chesterfield and District Friendly

Societies Council. This was duly held, and was followed by several others. It was hoped that these would lead to a fair and amicable settlement, but there were parties in the Friendly Societies at work from the first who were opposed to any fair consideration of the question, and these ultimately succeeded in persuading the Friendly Societies Council to send to this Union a resolution couched in such terms making it virtually an ultimatum that, unless it was acceded to, they would at once proceed to form a medical association. The terms of the resolution were so unreasonable in character that it was felt no good could possibly arise from further conferences, and consequently negotiations were discontinued. This was followed by notices being served by a number of lodges upon their medical officers.

The present state of affairs is that a number of these notices will expire at the end of the year, that the Friendly Societies have established a Medical Association and have secured the services of a medical practitioner.

The most satisfactory part of this dispute is the fact that all the members of the Union have remained loyal to each other, and that each member recognises he is helping, perhaps at some pecuniary loss, to fight a battle not only for himself but for the profession generally. It is gratifying to note that though the Union is a young society the laity are beginning to realise that they cannot trample down the profession as it has attempted heretofore, and disputes are now referred to the Union to be settled which before would only have been dealt with by the individual, and, as a rule, with grave injustice ensuing. This, with the exalted *esprit de corps* now prevalent, is one of the greatest benefits members of the Union have yet secured by uniting together for our common welfare.

Drs. Palmer and Allen also presented reports from Mansfield and Belper respectively, which were adopted.

The President referred to a dispute between Drs. Rainsbury and Mitchell on the one hand, and Drs. Crawford and Farman on the other, which had arisen in the Mansfield District with regard to certain professional and ethical questions associated with the medical appointments to the Teversal and Stanton Hill Collieries, which had been the subject of a conference held at Nottingham on December 2nd, and which had resulted in a satisfactory and amicable settlement. He read to the meeting a letter written to him by Dr. Bateman, the general secretary of the M.D.U., who attended the conference at the desire of all parties concerned, and in which he set out the conclusion at which the conference had arrived, that, after hearing the evidence of the gentlemen who felt aggrieved and the evidence in defence, it was clearly proved that the gentlemen against whom complaint had been made had not been guilty of any unprofessional or unethical conduct, and were entirely absolved from the grounds of complaint which had been alleged against them. The president added that he was pleased to report that he hoped an amicable settlement had been arranged, and a friendly relationship also been restored between the parties to the dispute, and he only regretted that the conference had not been held months ago, since it now appeared that if such a course had been taken the friction which was now shown to be groundless, and had so long existed between certain professional brethren in the neighbourhood, would have thus been easily removed. He moved that an account of the con-ference and the decision thereat be made known to the profession, and that Drs. Crawford and Farman be consulted as to the steps to be taken to effect their object.

Dr. E. H. Houfton seconded, and observed that the evidence given before the conference convinced all present that the allegations preferred could not be sustained. He suggested that the result of the conference should be communicated to the professional journals for publication.

Dr. Worthington, in supporting the resolution, said he thought it was only fair that everything should be done to make the decision widely known.

Dr. E. Wearne Clarke also supported the resolution, which was carried unanimously.

The General Secretary read a letter from Dr. Pope, of Leicester, inviting the Union to amalgamate with the Leicestershire Branch of the British Medical Association.

Dr. Mutch proposed that the matter be referred to the Chesterfield Branch.

Dr. E. Wearne Clarke seconded, and the resolution was carried without further discussion.

Later in the evening the Midland Medical Union held its annual dinner at the Hotel Portland. Among those present were Dr. J. Goodwin Shea (in the chair), J. Court, J.P., Martin, Wm. Dyson, J.P., S. Snell, J.P. Geo. Booth, J.P., Lewin, C. J. Palmer, Rainsbury, A. Hall, Houfton, E. W. Clarke, Peck, A. W. Shea, C. Palmer, Corkery, Burgess, S. Worthington, A. Palmer Croskery, W. J. Symes, Duncan, W. W. Robinson, Edmunds, Porter, Leary, Green, R. J. Pye Smith, B. Lee, J. H. Booth, and the general secretary, Mr. Geo. S. O'Rorke.

Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents].

THE CASE OF DR. RAINSBURY.

To the Editor of The Medical Press and Circular.

Sir,—I am desired by the Council of the Midland Medical Union to acknowledge through The Medical Press and Circular, the further contributions to the fund raised to aid Dr. Rainsbury in discharging the judgment given against him under the circumstances which have been reported in these columns, and which has fallen as a great hardship upon him.

In making this final appeal, I am desired by the Council to thank those who have so generously contributed, and to express the hope that some further contributions may be received towards the balance of £110 10s. 5d. which still remains.

I am, Sir, yours truly,
Geo. S. O'Rorke, Secretary.

December 17th, 1902.

„ Dr. J. H. Noble, Nottingham ...	1	1	0
	71	15	9

To the Editor of The Medical Press and Circular.

Sir,—We are directed by the Council of the Midland Medical Union to communicate to you for publication in your columns the result of a conference which has recently been held in Nottingham for the purpose of enquiring into and deciding upon certain professional and ethical questions associated with certain colliery appointments in the neighbourhood of Mansfield, and which have been the cause of local friction among members of the medical profession, and at which a satisfactory result was obtained.

The *raison d'etre* of the conference had reference to the manner in which certain medical appointments to the Silver Hill and Butcherwood Collieries of the Stanton Ironworks Company were held by Drs. Rainsbury and Mitchell, and were given to and held by Drs. Crawford and Farman in succession to Drs. Rainsbury and Mitchell, and in connection therewith the two latter gentlemen felt that they had cause for complaint on both professional and ethical grounds.

Prior to the conference all matters complained of were formulated by the parties preferring them, and agreed to by those against whom they were directed, as being the object of the conference proposed to be held to inquire into them.

The conference was held at the Victoria Station Hotel, Nottingham, on Tuesday, December 2nd, and there were present the following gentlemen:—Drs.

Oldham, Houfton, Palmer, Rainsbury and Mitchell as representing the Midland Medical Union; Drs. Crawford and Farman and Messrs. Piggford and Greatorex, the two last-named gentlemen being officials of the collieries referred to.

Dr. J. Goodwin Shea, J.P., of Chesterfield, President of the Union, presided, and Dr. Bateman, General Secretary of the Medical Defence Union, attended the conference at the desire of all parties with a view to elucidating the matter involved.

Evidence was given by Drs. Mitchell, Rainsbury, Palmer, Crawford, and Farman, Messrs. Piggford and Greatorex, and documentary evidence was also produced.

After an exhaustive inquiry, in which every party to the dispute was permitted to take part, and after all evidence for and against the truth of the charges was given, it was quite clearly proved that the charges made against Drs. Crawford and Farman could not be sustained, and were not borne out by the evidence given to support them.

As a result of the conference Drs. Crawford and Farman were entirely exonerated from any unprofessional and unethical conduct, and a complete, amicable and cordial settlement of all matters in dispute was arrived at.

We are directed to add that the Council of the Union desires that the result of the conference should be made known to the members of the profession. With this object Drs. Crawford and Farman have been consulted, and it is with their approval that this letter is written.

I am, Sir, yours faithfully,
J. Goodwin Shea, M.D.,
(President.)
George S. O'Rorke, LL.B.
(Secretary), Midland Medical Union.

Albion Chambers, King Street, Nottingham,
December 12th, 1902.

THE BATTLE OF THE CLUBS.

To the Editor of The Medical Press and Circular.

Sir,—Protracted wars become monotonous and even irksome, especially to those who have to pay for the shot. The most protracted battle I am acquainted with is "the battle of the clubs." The clubs believe in concentrating their forces, the doctors in guerilla warfare—a shot fired here and there—and occasionally one of the enemy is mortally wounded. The current number of the *British Medical Journal* contains a letter suggesting that certain members of the attacking force should be called "outsiders." Therefore we have traitors in our camp who forget that union is strength. Why cannot we concentrate our forces? Surely this can be done through our local medical societies. The opinions of members could be obtained. Then a mass meeting summoned to some convenient centre. Each medical society could send its representative or representatives. The expenses of delegates could be defrayed by the societies they represent. The expense would be small compared with the benefit which would accrue. The clubs would see that we were in earnest and act accordingly. As for the "outsiders," we know how to treat them. Nature knows how to act; we are all aware of the law, "survival of the fittest." We are causing the protraction of this war. We are the sufferers. It is not merely a matter of loss of £ s. d., but loss of prestige, loss of health, and loss of knowledge. Club mixtures do not tend to improve our therapeutical knowledge, and I fear that the diagnosis of club cases is often very superficial. Lung diseases are often diagnosed through coat, waistcoat, shirt, vests, and chest protectors. Abdominal pain or vomiting is charmed away by the soothing red mixture or remains until Nature diagnoses the case for us. This is not medicine, it is charlatanism, and we become charlatans.

I am, Sir, yours truly,
Dec. 22, 1902. Anti-Club.

Obituary.

THE LATE PROFESSOR YOUNG, GLASGOW.

Dr. John Young, who was appointed Professor of Natural History in Glasgow in 1866, and retired at the close of last session, died on the 18th inst., in his sixty-seventh year. He was one of the few remaining of the older race of Glasgow University Professors, only one of his contemporaries, Professor Ramsay, still holding office in the University. He was of Forfarshire family, and a graduate of Edinburgh University. At first he directed his attention to mental diseases, and was an assistant at Morningside Asylum, but gradually his interests turned more and more towards zoology and the allied sciences, and for the six years immediately preceding his election to the chair of natural history he was on the geological survey. Dr. Young did not limit his energies to his University work, but was a man of great versatility. He was a pioneer in the movement for the higher education of women. He had strong leanings to antiquarian lore, and was an authority on local archæology. Of strong musical tastes, he was a founder of the Scottish orchestra. Besides this, he took an active interest in all medical charities, as well as other social movements. He was the keeper of the Hunterian Museum, and in 1893 was honoured with the Presidency of the Educational Institute of Scotland.

STEWART STIRLING, M.D., F.R.C.S.E.

The death is announced at Edinburgh of Dr. Stewart Stirling, a well-known authority on diseases of the skin. Dr. Stirling, who was in the fifty-eighth year of his age was born at Drumessie, near Kilsyth, where his father and grandfather had been farmers, and was educated at the parish school of his native place, and for medicine at both Glasgow and Edinburgh Universities. He practised in Edinburgh for a few years, and afterwards left to fill an appointment as surgeon of the British Seamen's Hospital at Kronstadt, Russia. There he remained for twelve years. Returning to Edinburgh about twenty years since, he resumed general practice, and some years thereafter started in the High Street (afterwards removed to Drummond Street) what has developed into the Edinburgh Dispensary for Skin Diseases, Lauriston Place. The deceased gentleman, in addition to being a Fellow of the Royal College of Surgeons, was one of its examiners. He was the originator of the Edinburgh Goethe Society, and for many years its president.

WILLIAM STAINER, OF ENNIS.

We regret to have to announce the death of Dr. William Stainer, of Ennis, who died at the ripe age of ninety-four years. He was, we believe, the oldest medical practitioner, having been qualified as a L.A.H. in 1833. He lived to see five reigns—George III., George IV., William IV., Victoria, and Edward VII. When he commenced practice surgical anæsthesia was unknown, the stethoscope was just beginning to grow into favour, clinical thermometers were non-existent, and Currie's papers unread. Aseptic surgery was unthought of, and laudable pus was welcomed as a harbinger of life. The Broussian theory still dominated medicine, and the surgeon's chief reliance was on his lancet. Itinerant phlebotomists travelled the country bleeding man, woman, and child. Cuppers and phlebotomists were specialists, and leeches were one of the most expensive items in the hospital bill. The hard-worked dispensary medical officer had not come on the scene, and the poor were dependent on the charity of the generous rich, who provided dispensaries, and the free unstinted charity of the physician of the day. What a change! It is almost impossible to think of medicine struggling with disease unaided by the microscope, the Röntgen Rays, anæsthetics, antiseptics, and the clinical thermometer. Yet, without one of these, Dr. Stainer as a young man commenced practice. Not until 1855 did he seek further medical qualification, and he then became a L.F.P.S Glasgow. In the intervening years he had gradually won the confidence of his fellow towns-men and had become their trusted physician. During the remaining years of his life he more and more won their respect and held the place of both friend and physician, until full of honours and justly esteemed, he died with his strong intellectual powers unimpaired, mourned as a kind and courteous friend and as an experienced and skilful medical adviser. His death breaks the last link between the present generation of medical practitioners and those who so bravely and ably combated disease unaided by the scientific armamentarium of to-day.

MR. JOSEPH HARPER, L.R.C.P., M.R.C.S., J.P.

By the death of Mr. Joseph Harper, of Barnstaple, North Devon loses a skilful and highly-respected practitioner, and Barnstaple a man who for many years identified himself with the interests of this ancient borough, having several times occupied the position of Mayor.

Mr. Harper, whose burly frame and genial personality were familiar to every inhabitant for miles around, qualified in 1861, and went to Barnstaple soon after. He was Consulting Surgeon to the North Devon Infirmary, Medical Officer of Health to the Rural District Council, and President of Municipal Charities. Until recently he was Surgeon-Colonel to the 4th V.B.D.R.

Mr. Harper married the daughter of Captain Robinson, R.N., of Braunton. Mrs. Harper was killed about four years ago—the result of a trap accident while driving with her husband. He leaves several children, Two of the sons at least—Dr. John Harper, who practises at Barnstaple, and Mr. Charles Harper, who holds a colonial appointment on the West Coast of Africa—are well-known in the West of England on account of their brilliant play in the football field Another son, Dr. Walter Harper, is in practice at Braunton.

It is worth recalling that deceased once received a blackmailing letter from Neil Cream, the notorious criminal, and that he was instrumental in bringing him to justice.

NEW POCKET SURGICAL CASES.

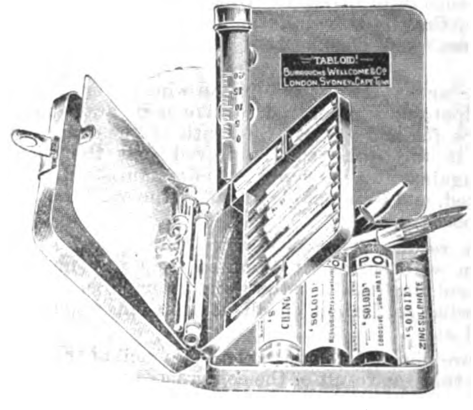
A Hypodermic "Article de Luxe."

A pocket hypodermic case which may fairly lay claim to manifest intrinsic superiority has been inspected by a trustworthy representative at the City offices of Messrs. Burroughs Wellcome and Co. It is not the sort of article to be distributed broadcast to the profession, sample wise, but it is admirably adapted for presentation—as "a small token of affection and esteem"—by a grateful patient or his friends The object in question, so far as the case and metallic fittings go, is of solid gold, the exterior thereof being—to borrow a phrase—exquisitely wrought. Its contents comprise a gold syringe with detachable finger grip, two gold-mounted platino-iridium needles, with the usual provision of accessories and hypodermic products. One's envious admiration for such a costly "art case" is tempered by the reflection that its possession would add another anxiety to existence.

BURROUGHS WELLCOME & CO
SOLOID

Hypodermic and Ophthalmic Pocket Case.

There really seems to be no limit to the ingenuity of designers in the direction of reducing the size of these indispensable pocket cases. The earlier cases of the kind were only "pocket" cases in the sense that, with patience, they could be insinuated into the pocket of an overcoat, but, passing through several intermediate stages, they culminate in the "Tabloid Hypodermic and Ophthalmic Combination Pocket Case," a specimen whereof has been submitted to us by Messrs. Burroughs Wellcome and Co. It only measures 3 × 3 × 1 in., so that it might be carried in the waistcoat pocket. Being made entirely of nickel-plated metal it can be kept perfectly aseptic, and it certainly ranks high for compactness and portability. The completely fitted case contains nine tubes of "tabloid" hypodermic products, nine tubes of "tabloid" ophthalmic products, four tubes of "soloid" antiseptic products, together with their patent hypodermic syringe, with finger-grip, two steel needles, one exploring needle, one gold lachrymal needle, pestle and mortar, two camel-hair brushes' one dropper and a vulcanite rod. If preferred, the B. W. & Co. All-Glass Aseptic Syringe will also fit this case. As will be seen, the case is an emergency equipment in itself, and its finish approaches perfection.



Literature.

GRANT ON THE FACE, MOUTH, AND JAWS. (a)

We do not believe that books of the kind before us are in demand among dental students either in this country or the United States; and we do not attempt to account for the fact that the author—an experienced teacher—should have wasted his time in compiling this volume. For the student who proposes to confine himself to the practice of dentistry, and who is preparing for a dental examination, it is much better to gain his surgical knowledge from an ordinary work on general surgery. There he gets full information on the principles of surgery and pathology, and he can easily pick out the special subjects—diseases of the mouth and jaws—with which he should be especially acquainted. There is a vast amount in the book before us, ranging from "Hydrophobia," "Epilepsy," and "Apoplexy" to "Malignant Lymphoma," and a whole series of morbid growths which occur about the face and jaws, that have no relation whatever to the practice of dental surgery, and that are never brought under the notice or care of the dental practitioner in the pursuit of his specialty. On the other hand, such subjects as neuralgia of the face and empyema of the antrum, of constant concern to the dentist, are too briefly dealt with to be of adequate use to the student; whilst all through the attempt to b concise leads to much obscurity, owing to the author's apparent lack of literary skill, or want of sufficient care in giving the quality of objectivity to his writings. The book contains a large number of illustrations, but of these a small proportion only can be of any use to the dental reader.

(a) "A Text-book of Surgical Principles and Surgical Diseases of the Face, Mouth, and Jaws, for Dental Students." By H. Horace Grant, A.M., M.D., Professor of Surgery and of Clinical Surgery in Hospital College of Medicine, &c. Illustrated. Philadelphia and London: W. B. Saunders and Company. 1902.

Medical News.

The Strike of Pharmacists in Galicia.

The chemists' assistants who struck for shorter hours and better pay have carried the day, the masters having given way. This is, no doubt, due to the fact that pharmacy in this country is a close preserve, and that there were no potential "blacklegs" to assist the masters in holding out They are compelled by the terms of their license to carry on the work, and this was almost impossible when single-handed. On the other hand it must be admitted that there was ample margin for improvement, the assistant pharmacists being expected to work almost continuously for small pay.

Arsenic or No Arsenic?

A brewer was charged at Stourbridge the other day with selling beer containing arsenic, the analysis having been made by the County Analyst for Warwickshire. The Staffordshire County Analyst, on the other hand, failed to discover any arsenic in the sample, and his result has since been confirmed by the Government Analyst. The charge was therefore dismissed, with £26 costs against the prosecutors.

A Futile Inquest.

An example of how not to conduct an inquest was set by the coroner's jury at Bilston last week when inquiring into the death of an infant. Two practitioners had seen the child, and both refused to certify the death, one of them referring the parents to the police. In spite of this fact a verdict of "natural causes" was arrived at apparently without either doctors being called upon to give evidence or without, under the circumstances, the indispensable formality of an inquest.

Medical Congress at Cairo.

The first Egyptian Medical Congress was opened by the Khedive, at Cairo, on Friday last, in the presence of several hundred representatives of, and delegates from the profession all over the world. The object of the Congress is to study the diseases of hot climates, and a number of important contributions are to be presented. The situation of Cairo lends itself admirably to the social side of such a meeting, and various attractive functions have been organised.

The New Buildings of the Adelaide Hospital.

His Excellency the Lord Lieutenant opened last week the new Operating Theatre, Nurses' Home, and Dispensaries connected with the Adelaide Hospital, Dublin. The operating theatre has cost £3,500, and will compare more than favourably as to its suitability, efficiency, equipment, or beauty with that of any hospital in the United Kingdom. It is in every way up to date, and worthy of the traditions of the Adelaide Hospital and of the scientific skill and ability of the members of the noble profession who will use it in the exercise of their duties. The Nurses' Home, which His Excellency had also been asked to open, supplies a want which has been much felt of late years, as the old "Home" accommodation had become utterly inadequate. In the same wing, on the ground floor, a new dispensary has been constructed and is now opened for the outdoor patient department. This dispensary was contemplated as far back as 1887, and a considerable sum towards it had been raised that year as a memorial of her late Majesty's Diamond Jubilee. The chairman announced that the committee had obtained the sanction of her Gracious Majesty Queen Alexandra to use her name in connection with the new Nurses' Home, and that it would be named by His Excellency that day, and known for the future as "The Alexandra Memorial Home." His Excellency, in the course of a speech, referred to the late illness of the Countess of Dudley, and to his gratitude to her medical advisers for their skilful assistance. He then declared the new buildings open. The proceedings terminated with a vote of thanks to His Excellency.

Death Under Chloroform.

A publican at Bury died last week from chloroform, administered for the purpose of an operation on the larynx. The usual verdict was returned.

Prosecution for Non-Notification of Typhoid Fever.

Dr. G, W. T. Clarke, of Uxbridge, was prosecuted last week for having failed to notify a case of typhoid fever. Dr. Clarke stated that he had sent the certificate by post as soon as he had made the diagnosis, but it transpired that the certificate did not reach the medical officer of health until a month later. The envelope bore the later date, and it was suggested that it had in some way been delayed in transit. The Bench, however, pointed out that the responsibility of delivering the notification lay with the defendant, and imposed a fine of £1 with £3 3s. costs.

Dispensing Fatalities.

Several dispensing fatalities have been reported from various parts of the country during the last few days. Among them we may note the death of a farmer at Surfleet from the effects of strong solution of ammonia dispensed in error for acetate of ammonia, and that of a young lady at Edinburgh from the effects of strychnine dispensed for phenacetin in a headache powder.

Pass Lists.

Society of Apothecaries of London.

During the December examinations the following candidates passed in:—

Surgery: J. E. L. Bates (Sections I. and II.), V. E. M. Bennett (Section I.), A. N. Collier (Section I.), D. Cotes-Preedy (Section I.), W. B. Harris (Section II.), J. Hunter (Sections I. and II.), E. Knight (Section I.), M. L. Pethick (Sections I. and II.), L. C. A. Savatard (Sections I. and II), G. B. S. Soper (Section II.).

Medicine: V. E. M. Bennett (Sections I. and II.), J. C. O. Bradbury (Sections I. and II,), W. C. P. Bremner, L. Courtauld (Sections I. and II.), E. H. Griffin (Sections I. and II), J. D. Keir (Section I.), E. Knight (Sections I. and II.), G. B. S. Soper (Section I.), J. A. W. Webster (Sections I. and II.), G. Wilmorsdoeffer (Section I.).

Forensic Medicine: V. E. M. Bennett, J. C. O. Bradbury, E. H. Griffin, E. Knight, M. L. Pethick, H. S. Tumber, J. A. W. Webster, G. Wilmersdoeffer.

Midwifery: J. E. L. Bates, V. E. M. Bennett, W. E. Denniston, R. S. Dollard, A. C. George, E. H. Griffin, O Gutermann, E. Knight, W. Martin, H. G. Peel, M. L. Pethick, L. S. Shoosmith, G. Wilmersdoeffer. The L.S.A. diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—E. H. Griffin, J. Hunter, and J. A. W. Webster.

Trinity College, Dublin.

The following candidates were successful at the Michaelmas Examinations in Public Health:—

Diploma in Public Health, Part I: Carter, James E., M.B., B.Ch., B.A.O.; Kennan, Richard H., M.D.

Part 2: Carter, James E., M.B., B.Ch., B.A.O.; Kennan, Richard H., M.D.

Notices to Correspondents, Short Letters, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature* or *initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Contributors are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Original Articles or Letters intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Reprints.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

Mrs. B.—The prices charged in nursing homes vary. Some are as low as three guineas a week, but the majority are much more. Included in the charges are board and lodging and nursing attendance: medicines, dressings, special foods, &c., are usually extra.

Dr. Laloir.—There is, in our opinion, no ambiguity in the bond. It may press hardly upon our correspondent, but if he be wise he will accept the situation.

Lupis Divinus.—Our correspondent has been ill-advised. The matter should now be allowed to drop.

Country Member.—The ideal qualification for a London coroner is that he shall be a medical man who has been called to the Bar. If to these qualifications it be added that he has served the office of deputy-coroner in one of the Metropolitan districts, his claims for promotion to a full coronership are very heavy; almost without exception the present London coroners have been deputies.

CLIPPINGS FROM LAY EXCHANGES.

The Association Sets.

"Dr. C—— left for Omaha Tuesday to attend the State Medical Association which sets the sixth, seventh, and eighth. As president of one section he is billed for a paper on gyneacology and absteterics. The Dr. takes great pleasure in such gatherings."—*Albion* (Neb.) *Argus*.

Dr. R. W. L.—Egg lemonade is a nutritive and refreshing drink for febrile patients. It is prepared in the following manner:—Take two lemons, peel them twice, discarding the white layer and using only the yellow rind. They are sliced and placed with the yellow rind and a little sugar in a jug, and a pint of boiling water is poured thereon and allowed to cool, occasionally stirring. When it has cooled to about 100° F. insert an egg-whisk and gradually pour in the white of an egg, whisking vigorously all the time; strain through muslin while still hot, and serve cold.

DOCTORS OF OPTICS.

According to *American Medicine* the diploma of doctor of optics, price thirty shillings, is being hawked round in the United States. "No questions asked." The use of the ophthalmoscope and retinoscope and the ability to diagnose and treat all errors of refraction is taught by correspondence without extra charge. British optical papers please copy. Our correspondent suggests that the London Spectacle Makers Company might be willing to take a job lot of the diplomas for distribution among its *alumni*.

CONSUMPTION IN GERMANY.

In no country in Europe has the fight against consumption been waged with so much persistence and success as in Germany. The following table shows the decline in the death statistics from consumption since 1876, the year in which accurate statistics were first compiled. The number of deaths refer to ten thousands of population:—

	1876	1901
Crefeld	62	37
Breslau	61	38
Danzic	35	16
Aachen	21	12
Elberfeld	164	53
Charlottenburg	25	19

Here are six representative cities scattered throughout the Empire, and the statistics show at a glance the immense progress which has been effected in twenty-five years.—*The Leisure Hour* for January, 1903.

Meetings of the Societies, &c.

LONDON.

Saturday, December 27th.

Royal Institution of Great Britain (Albemarle Street, W.).—3 p.m. Prof. H. S. Hele-Shaw: On Locomotion, on the Earth, through the Water, in the Air. (Christmas Lectures adapted for Young People.)

Appointments.

Austen, Harold, M.D., B.S.Lond., M.R.C.S., L.D.S., Assistant Dental Surgeon to St. Bartholomew's Hospital.

Child, Herbert, M.R.C.S., L.S.A.Lond., Surgeon to the Department for Diseases of the Throat, Nose, and Ear, Reading Dispensary.

Hamilton, Geo. G., M.B., F.R.C.S.Eng. & Edin., Honorary Surgeon to the Liverpool Royal Infirmary.

Mackenzie, Dudley M., M.B., Ch.B.Aberd., Junior Resident Medical Officer to the Croydon General Hospital.

Nuttall, Alex. W., F.R.C.S.Eng., Surgeon to Out-patients to the Queen's Hospital, Birmingham.

Pegler, L. Hemington, M.D.Edin., M.R.C.S., Honorary Surgeon for Diseases of the Ear, Nose and Throat to the Clergy Orphan Corporation School for Girls, St. Margaret's School, Bushey, Herts.

Phillips, Hugh R., M.D.Edin., Second Anæsthetist to the Italian Hospital, Queen's Square.

Roberts, H. M., L.R.C.P. & S. Edin., L.F.P.S.Glasg., Medical Officer for the Parish of Stevenston, Landward Portion.

Robinson, J. F., F.R.C.S.Eng., L.R.C.P.Lond., Senior Resident Medical Officer to the Croydon General Hospital.

Vacancies.

Birkenhead Borough Hospital.—Senior Resident Male House Surgeon. Salary £100 per annum, with board. Applications to Chairman, Weekly Board.

Bridgwater Infirmary.—House Surgeon. Salary £80 a year, with board and residence. Applications to Mr. Edward Trevor, Honorary Secretary, Bank Chambers, Bridgwater.

Brecon and Radnor Asylum, Talgarth, R.S.O.—Assistant Medical Officer. Salary £140 per annum, with furnished apartments, board, attendance, and laundry. Applications to the Medical Superintendent.

Cahirciveen Union.—Dispensary Medical Officer. Salary £150 per annum, and £15 a year as Medical Officer of Health, together with the usual Vaccination Fees. Immediate applications to T. C. Fitzgerald, Clerk of Union. (See Advt.)

Carlow Union.—Assistant Nurse. Salary £20 per annum. Applications to the Presiding Chairman by the 2nd prox. (See Advt.)

Carmarthenshire Infirmary. Resident Medical Officer. Salary £100 per annum, with furnished apartments, board, attendance, fire, gas, and washing. Applications to Howell Howell, Secretary.

Essex and Colchester Hospital.—House Surgeon. Salary £100 per annum, with board, washing, and residence in the Hospital. Applications to C. L. Becher, Secretary.

Great Yarmouth Hospital.—House Surgeon. Salary £90 per annum, with board, lodging, and washing. Applications to Richard F. E. Ferrier, Hon. Secretary, 33, Hall Plain, Great Yarmouth.

Lancashire County Asylum, Winwick, Warrington.—Assistant Medical Officer. Salary commences at £150 per annum, with furnished apartments, board, attendance, and washing. Applications immediately to the Medical Superintendent.

North Staffordshire Infirmary and Eye Hospital, Hartshill, Stoke-upon-Trent.—House Surgeon. Salary £120 per annum, with furnished apartments, board, and washing. Applications to the Secretary and House Governor.

Nottingham General Hospital.—Assistant House Surgeon. Salary £100, with board, lodging, and washing in the Hospital. Applications to the Secretary.

Notts County Asylum, Radcliffe-on-Trent.—Assistant Medical Officer. Salary £130. Applications to the Medical Superintendent.

Palmer Memorial Hospital, Jarrow-on-Tyne. House Surgeon. Salary £120 per annum, with board and residence. Applications to the Secretary.

Sir Patrick Dun's Hospital.—Assistant Surgeon. Immediate application to the Secretary, Dublin. (See Advt.)

The Cancer Hospital (Free), Fulham Road, S.W.—Junior House Surgeon. Salary £70 per annum, with board and residence. Applications to Fred. W. Howell, Secretary.

Watford Joint Hospital Board.—Matron. Salary £100 per annum, with board and residence. Applications to the office of the Board, Watford Place, Watford.

Birth.

Slaughter.—On Dec. 17th, at 76, Brondesbury Road, N.W., the wife of E. A. Slaughter, M.R.C.S., of a son.

Marriages.

Hale—Wadd.—On Dec. 17th, at St. Matthias' Church, Richmond Hill, Major G. E. Hale, D.S.O., R.A.M.C., to Kathleen, youngest daughter of Dr. Wadd, of Richmond Hill, Surrey.

Hanley—Shelley.—On Dec. 18th, at St. Thomas's Church, Dudley, Worcestershire, Richard George Hanley, M.B., Major Royal Army Medical Corps, to Grace Lilian, daughter of the late Rowland Shelley, Esq.

Malcolm—Topham.—On Dec. 17th, at the Church of St. John Baptist, Penzance, John D. Malcolm, F.R.C.S.Ed., of 13, Portman Street, London, W., to Frances Sophia, widow of Edward C. Topham, of Kilkhampton, N. Cornwall.

Panting—Hepburn.—On Dec. 17th, at St. Mary's Church, Aldridge, Laurence Christopher Panting, M.D., M.A.Oxon, of Truro, to Jane Agnes (Nina), younger daughter of the late Archibald Hepburn, Esq., and Mrs. Hepburn, of The Moot House, Aldridge.

Phillips—Heron-Watson.—On Dec. 18th, at St. Andrew's Church, Drumsheugh Gardens, Edinburgh, Robert Walter Douglas Phillips, The Cottage, Chelford, Chester, to Isabella Edith (Ida), younger daughter of Patrick Heron-Watson, M.D., LL.D., F.R.C.S., Honorary Surgeon to the King in Scotland.

Stone—Sinclair.—On Dec. 17th, at St. Jude's Church, South Kensington, Major Charles A. Stone, eldest son of Mr. W. A. Stone, late R.N., to Edith Annie, only daughter of Surgeon-General and Mrs. E. M. Sinclair, of 33, Nevern Square, S.W.

Deaths.

Boreham.—On Dec. 14th, at his residence, Elm Bank, Teignmouth, William Godman Boreham, M.D., aged 53 years.

England.—On Dec. 16th, at West Hayes, Winchester, William England, M.D., F.R.C.S., aged 79 years.

Paris Clinical Lectures.

THE HEART IN ACUTE ARTICULAR RHEUMATISM.

By Dr. ERNEST BARIE,
Physician to the Laennec Hospital.

[SPECIALLY TRANSLATED FOR THE MEDICAL PRESS AND CIRCULAR.]

In his "Clinical Treatise on Acute Articular Rheumatism, and the Law of Coincidence of Inflammations of the Heart with this Disease," published in 1840, Bouillaud, discussing afresh the relationship between affections of the heart and acute articular rheumatism, a view which he has maintained since 1836, described the intimate connection between these two conditions in two short and rigidly-defined laws.

1. In acute, violent, general articular rheumatism the coincidence of endocarditis, pericarditis, or endo-pericarditis is the rule, the non-coincidence being the exception.

2 In acute articular rheumatism of the moderate, partial, and apyretic type, the non-coincidence of endocarditis, pericarditis, or endo-pericarditis, is the rule and their coincidence the exception.

These two laws remain, on the whole, unattackable in their general significance, but the terms are too absolute and too rigid; for if we were to insist on this, it would be easy to show that the subacute forms of articular rheumatism are but too often complicated by organic affections of the heart.

Be this as it may, the narrow relationship which exists between endo-pericarditis and acute articular rheumatism is at the present time unanimously admitted by all clinical observers; but, on the contrary, in chronic rheumatism, the problem becomes singularly involved, and deserves to be closely studied Let us first see what various observers say with regard to this subject.

In an important paper, the *résumé* of a contribution read before the Biological Society, M. Cornil in nine cases of chronic articular rheumatism, followed by post-mortem examination, found signs of pericarditis four times -twice it was acute pericarditis which had developed during the attack of rheumatism, and twice pericarditis of old standing, which had given rise to extensive adhesions accompanied by obliteration of the pericardial sac, complete in one case, partial in the other. These very remarkable observations, which were collected at the Salpetrière Hospital, in Charcot's wards, are worthy of our attention.

The first case of acute pericarditis occurred in a woman, æt. 66, in whom rheumatic arthritis was complicated by an enormous abscess in the leg, which caused her death. At the post-mortem examination hæmorrhagic pericarditis was discovered; the pericardium was filled with a sanious liquid, containing fatty globules. The two surfaces of the serous membrane were covered by fibrinous pseudo-membranes, non-adhesive and recent. The heart was big and its muscular fibres were of a yellow colour; it contained black fluid blood.

The second case is particularly interesting. It was that of a woman, æt. 29. who had been suffering from chronic articular rheumatism ever since she was twelve years of age. In this case the pericarditis supervened suddenly with a rigor of violent præcardiac pain and well-marked dyspnœa. The cardiac area was the seat of tumultuous pulsations; at the base there was a creaking sound like that of new leather with both sounds, and at the apex a systolic murmur. Later on, in spite of repeated wet cuppings over the præcardiac area and the administration of digitalis, the patient complained of great pain in the region of the apex, indeed the pain was such that she was unable to lie on her back, and was obliged to sit up in order to breathe. On auscultation the pathological noises disappeared little by little, but it was observed that the two ordinary sounds of the heart were dull and far apart. After a temporary improvement lasting a month the patient was again admitted to the infirmary. At this stage the cardiac beats were very tumultuous and arhythmic, and the whole præcardiac area was absolutely dull on percussion. This serious condition was further complicated by pleurisy, intense prostration and convulsions which culminated in death. At the post-mortem the pericardium was found to be enormously distended, and to contain a considerable quantity of blood-stained liquid; its two surfaces were covered by a villous exudation, which histological examination showed to be vascularised neo-membranes. The heart was large and soft, its cavities were dilated, but the orifices were not damaged. The ventricular walls, thin and softened were of a yellow colour Under the microscope the original fibres were seen to be granular, and had partly lost their striation; these granulations involved the muscular fibres themselves, were of a yellow colour and composed of fat In other words, there existed a hæmorrhagic pericarditis accompanied by fatty degeneration of the myocardium complicated by pleurisy and albuminous nephritis.

The two cases of chronic pericarditis can be related in a few words: in both patients the aorta was atheromatous, and in one case the aortic lesion involved its origin as well as the aortic valves. These lesions entailed aortic insufficiency. In both cases, indeed, hypertrophy of the left ventricle and fatty degeneration of the myocardium was noted as the result of the pericarditis.

The connection between chronic articular rheumatism and diseases of the heart is established by numerous and well-authenticated observations. As regards their frequency, these cardiac affections are certainly rare, and there is in this respect nothing that can be compared with what we observe in acute articular rheumatism This may explain why certain authors such as Vidal, Fuller, Durand-Fardel, Guéneau de Mussy, &c., who have studied the manifestations and clinical forms of chronic rheumatism very closely, do not even mention the existence of these affections of the heart. M. Lancereaux, establishing a parallel between acute articular rheumatism and chronic arthritis, recognises that, in the former, the danger lies in the frequency of the mitral lesions; while in the latter, what one has to fear is arterio-sclerosis, so frequently met with in these patients, associated or not with lesions of the aortic orifice. Professor Jaccoud had long before expressed the same opinion, viz., that affections of the heart do not often occur in connection with chronic arthritis. "We do not," he says, "meet so much with valvular lesions; it is pericarditis, and arterial atheroma, with its consequent lesion, hypertrophy of the heart." He clearly recognises, nevertheless, the comparative frequency of pericarditis.

Charcot appears to have been one of the first (from 1863) to recognise the comparative frequency of organic affections of the heart in chronic articular rheumatism. In a paper, published in 1867, he insisted on the fact that endocarditis and pericarditis unquestionably occurred in a certain proportion of cases of chronic articular rheumatism; that these affections were of a similar character to those met with in acute rheumatism, and they develop in preference, during the acute outbreaks of the affection which approximate in a certain degree the acute stage. Having made this last statement, which has become classic, he adds this very important fact to the effect that he has collected a large enough number of observations in which endocarditis developed in the course of chronic rheumatism without this affection having ever passed through an acute stage.

Be this as it may, and without discussing for the time being the pathogenesis of these affections of the heart, we must mention that they have most frequently been observed in female subjects, a fact which will not cause surprise if we bear in mind that chronic arthritis is specially frequent in women. Men, however, are not as free from it as we might at first imagine; for out of twenty-three observations of heart lesions there are twenty in which the sex is indicated—fifteen women and five (that is 25 per cent.) men.

Chronic articular rheumatism accompanied by an affection of the heart occurs at all ages, although it more frequently attacks the aged—sixty years (Charcot), seventy-one years (Mauriac), seventy-eight years (Charpentier), eighty-four years (Charcot, Ball), &c. It is also met with during adolescence—ten years (Barthez), sixteen years (Dally), seventeen years (Cornil), and even in very young children (Stoicesco, Charon).

All affections of the heart are not met with in connection with chronic arthritis deformans. According to Jaccoud and Charcot, pericarditis is met with more frequently, and this opinion is generally admitted; but from the cases we have just been studying it will be seen that endocarditis is fully as frequent. Next come the following affections, which are generally associated with the preceding complaints, hypertrophy of the heart, degenerative changes in the myocardium (fatty degeneration, hypertrophy), and lastly, cardio-sclerosis.

Pericarditis is sometimes dry (Barthez, Mauriac), sometimes accompanied by effusion; in the former case, all varieties are met with, from the simple soft, fibrinous pseudo-membranes, sometimes very extensive but easily detached (Ball), to the extensive thick adhesions of the two layers, with complete obliteration of the pericardium (Cornil), that is to say, the most complete type of cardiac symphysis. Pericarditis with effusion seems to have a predilection for the hæmorrhagic form; in the case recorded by Charpentier it simply took the form of a blood-stained serous liquid, filtering through the network of exudation; but in Cornil's two cases there appears to have been a genuine effusion of blood.

Endocarditis involved the mitral valve four times only, and among these cases I remember a very curious one reported by Charon, that of a little girl, æt 4, in whom the endocarditis was both parietal and valvular. Aortic lesions are more frequent (seven cases); and with one exception the lesion met with was aortic insufficiency. The patients suffering from this lesion are either adults or old people, but young subjects, and even adolescents are not altogether free from it, since the patient observed by Ollivier was twenty three years of age, and the case related by Dally was a lad of sixteen.

I will not discuss the other cardiac changes—hypertrophy, dilatation, fatty degeneration, polysarcia, &c.—these lesions being usually associated with those of the endocardium and pericardium. I will not dwell any longer on the symptoms or evolution of these different affections of the heart; they all end, after a variable period, in functional failure of the myocardium or asystole. I now arrive at the most recondite part of this problem, viz., the pathogenesis of these affections of the heart in chronic articular rheumatism.

No comparison can be made with acute articular rheumatism. We know, indeed, that the microbial origin of the latter is gradually gaining in probability in spite of the negative researches of Sänger and of Weichselbaum, which are, moreover, contradicted by the positive results of Acholme, Lucatello, Triboulet, Thiroloix, Pic, Lesieur, &c. Doubtless the morphology and biological characters of this microbe are still unknown, but its influence on the prevention of endocarditis is none the less extremely probable; no such factor can be invoked in the case of arthritis deformans. By close study of patients suffering from this last complaint, we can divide them into three distinct groups:—

In the first, the cardiac affections of old standing appear to walk hand in hand with chronic rheumatism, but without any direct connection therewith, for we find in the antecedents of the patient evidence of pathological influences such as typhoid fever, syphilis, &c., to which we may attribute the cardio-sclerotic affections—scarlet fever may also stand in causal relationship with erysipelas, diphtheria, puerperal fever, &c.

In the subjects of the second group it is clear from a study of the evolution of the cardiac affection that it commenced during an acute or subacute rheumatic attack, which had complicated the chronic arthritis. This being the case, these come under the law formulated by Bouillaud, and it is by this pathogenesis that the majority of authors incline to explain the coexistence of affections of the heart and chronic articular rheumatism.

Lastly, in the third category there occur the much rarer cases in which the arthritis deformans appears as such from the first, without being preceded or giving rise during its evolution to any acute or subacute manifestation. Such are, for instance, the cases mentioned by Beau and Charcot, such, also, is the case of our patient in the Tenon Hospital, and of the woman who is at the present time under our care. The interpretation to be placed on the cases comprised in this third group is by no means certain, and we must make a further subdivision. Many of these patients are, as a matter of fact, either aged, markedly atheromatous, or middle-aged people with all the symptoms of premature arterio-sclerosis. In all of them the cardiac lesions are, as a rule, complex—cardio-sclerosis, dilatation of the heart, aortic lesions, and sometimes lesions of the coronary arteries with induration of the temporal and radial arteries, &c. These cardio-vascular changes are all part and parcel of the general process of arterio-sclerosis, and chronic rheumatism has played no appreciable pathogenic *role* in the production of the cardiac affection. In other patients, large eaters, alcoholic, or obese, we must bear in mind the deleterious action of alcohol in order to explain the degeneration of the myocardium and fatty surcharge of the heart which is seen at the post-mortem examination of so many of those who have suffered from deforming chronic polyarthritis.

There still remains one group of patients who do not come under any of these heads, who are neither old nor suffering from arterio sclerosis, and to whom what we have just said does not apply; such are, for example, adolescents and young children, who are far from being immune from attacks of chronic arthritis, as you are aware.

The difficulty of interpreting such cases is more so since we are far from certain of the exact nature of chronic articular rheumatism. Admitting that acute articular rheumatism can, under certain conditions, leave more or less permanent traces of its passage, it is at the present time generally recognised that acute rheumatic arthritis differs entirely in its nature from chronic articular rheumatism, which appears to have usurped the name of rheumatism. As a matter of fact its relationship to acute articular rheumatism is always very obscure.

As to its intimate nature it appears that we must attribute chronic arthritis to two distinct factors.

Struck by the resemblance between amyotrophies following chronic rheumatism, and the muscular atrophies of nervous origin, M. Debove remarks that the articular and muscular lesions of chronic rheumatism might well be ascribed to changes in the central nervous and peripheral nervous systems. It is with the same thing in view that Dr. Lancereaux says: "The lesions of chronic rheumatism bear the closest resemblance to those we sometimes meet with in locomotor ataxy, general paralysis, certain affections of the spinal cord and nervous cords; they are certainly due, at their starting point, to some disturbance of trophic innervation."

However, if this point of view is not admitted—since pathological anatomy does not establish it, but which I know to be a fact—we are obliged to regard chronic rheumatism as one of those complaints due to a slowing down of nutrition, and this idea is the more plausible since two of these affections may, like chronic arthritis, be complicated by cardiac lesions—gout and diabetes for instance. The former, like rheumatism, is accompanied by chronic degeneration of the myocardium, sometimes by valvular endocarditis (Lobstein, Coupland), and even by pericarditis with effusion (Trousseau). In diabetes also, the heart is often changed, according to Saundby, in the proportion of 60 per cent. Thus in deforming chronic arthritis we meet with fatty degeneration, hypertrophy of the heart, cardio-sclerosis, and lastly, but more rarely, valvular endocarditis, of which M. Lécorché observed fourteen cases (ten in women and four in men).

Thus these two disturbances of nutrition display in common this liability to the same acute affections of the heart, and these—it is logical to suppose—are due to the effect on the circulatory apparatus of the fundamental dyscrasiæ. But though these dyscrasiæ have for a long time been recognised with regard to gout and diabetes (uricæmia, hyperglycæmia) in connection with chronic rheumatism, on the contrary, we have not up to the present time obtained any precise data. I am aware that a case related by Böcker, and referred to by Charcot, is often quoted; that of a patient suffering from chronic rheumatism, in whose urine was discovered a marked diminution in the normal proportion of phosphate of lime. While in the blood this salt was four times more abundant than normal. As is always the case, uric acid was not present in the blood. In spite of this interesting case, we must bear in mind that hæmatology and the study of secretions in chronic rheumatic polyarthritis have up to the present time given very unsatisfactory results. This uncertainty does not, however, justify us in abandoning the theory which we have just enunciated, and which above all others appears plausible and likely to throw light upon the coincidence between cases of chronic articular rheumatism and organic affections of the heart.

THE ETIOLOGY OF TUBERCULOUS PERITONITIS. (a)

By EDMUND CAUTLEY M.D., Cantab, &c.,

Physician to the Belgrave Hospital for Children, &c.

On the grounds of scientific precision all forms of inflammation of the peritoneum due to the tubercle bacillus should be included under the name of "Tuberculous Peritonitis."

Preference is sometimes given to the name "Tuberculosis of the Peritoneum," for peritonitis suggests that the essential feature is an inflammation, whereas the tuberculous infection is the great characteristic. Both the clinical signs and symptoms are rarely those which we are accustomed to associate with a diagnosis of peritonitis. In one variety, the most common one in children, the peritoneum may be studded with grey tubercles without the spread of inflammatory changes from the tubercles to the peritoneum. This we may omit from the discussion as being part of a general blood infection, an acute miliary tuberculosis. Death usually takes place before the onset of any definite abdominal symptoms. Should the illness be more prolonged the grey tubercles may undergo caseous degeneration and there may result a certain amount of peritonitis and exudation. Strictly speaking, the process, even in the earliest stages, is an inflammatory one, for a tubercle results from inflammatory changes initiated by the irritation of the tubercle bacillus. Omitting this variety we have three more or less distinctive types of the disease, any one of which may be either localised or generalised. This classification I suggest as the most simple one for the purposes of a discussion.

1. Adhesive peritonitis.
2. Peritonitis with effusion of (*a*) serum, (*b*) pus.
3. Caseous or ulcerative peritonitis.

From the etiological point of view no such distinction is necessary, and my remarks will apply to every form of tuberculous infection of the peritoneum. The etiology of the disease is that of tuberculosis generally, with the addition of a few special points indicating why the peritoneum is attacked.

Gentlemen, the child is the product of inheritance modified by environment. In the case of disease due to microbial infection we have the same idea expressed in another form when we speak of "the seed and the soil." The latter phrase does not quite cover the ground, for it omits special reference to the manures modifying the nature of the soil.

By the *soil* I mean the primary physical constitutional state of the subject dependent on inheritance.

By the *manures* I mean all those influences or modifications of the soil, the constitutional state, as a result of environment.

The *seed* is the tubercle bacillus, for that, and that only, can give rise to tuberculous disease.

Inheritance.—Like many of the beliefs of our ancestors, the belief in the inheritance of tuberculosis has been scoffed at and deemed of no account. On the other hand, it has undoubtedly received undue prominence as an etiological factor, and has caused much too gloomy a prognosis to be given in the case of children of tuberculous parentage. The term inheritance in this connection means one of two things:—

1. Either the disease is directly transmitted from parent to child through the medium of an infected germ cell or maternal blood supply.
2. Or the child inherits a certain peculiarity or delicacy of structure which renders it more susceptible to the particular disease.

Vague and indeterminate as the latter explanation sounds, it is probably true of the inheritance of disease. The physical strength and health of the child, and its power to resist disease, depend primarily on those of its ancestors. Whether the child of tuberculous ancestry is or is not more prone to develop tuberculosis is a moot point, which will be referred to subsequently.

Taking the case of the father first, it has been shown that the tubercle bacillus may exist in the semen, *e.g.*, in tuberculous disease of the vesiculæ seminales. It is almost inconceivable that the microscopic spermatozoon can actually contain the bacillus, even in spore form, and convey it to the ovum. Much more probably the infection of a sperm cell would impair its nutrition and render it useless for the purpose of impregnation.

Similarly, it is equally improbable that an infected ovum could be satisfactorily impregnated and carry out developmental processes. The bacillus has been actually found in the ovum in one instance by Baumgärten, who artificially fecundated a rabbit with tuberculous semen. But maternal inheritance stands upon a very different footing. For nine months or so of pre-natal existence the future child is in the closest of all possible contact with the mother. During the whole of this period it receives its blood supply from the mother, filtered, it is true, for the greater part of the time through the placenta. Yet even human filters are sometimes imperfect. Supposing the mother to be tuberculous, it is by no means improbable that the placenta may become affected. Its nutrition may be sufficiently impaired to permit the passage of the bacillus from the maternal blood to that of the fœtus. Or the placenta may be actually tuberculous. Gärtner, as the result of inoculating the mother, intra-peritoneally or intravenously, produced tuberculosis in young mice. A calf has been found tuberculous at birth. Bacilli have even been found in the human fœtus removed by Cæsarian section from a tuberculous mother. Many infants show such advanced tuberculosis of the lungs (and note that it is usually of the lungs) a few months after birth as to render fœtal infection a suggestive explanation. On the other hand, in most of these instances, the mother has given no evidence of tuberculosis, and there has often been a history of exposure to infection. Even if there be no tuberculosis in the mother, as in the case of a child of six months under my care, in whom extensive tuberculosis of the lungs was found, the probability of direct infection is enormous. In a case of Stiegenberger's, a babe died at five months from extensive tuberculosis. The parents were healthy, but the babe had been nursed by a tuberculous nurse.

(a) Opening a Discussion before the Society for the Study of Disease in Children, December 12, 1902.

In the bulk of supposed inherited cases of tuberculosis we shall find on careful investigation evidence of direct infection, rather than of infection through the medium of a germ cell or maternal blood supply. Inheritance of the disease is so rare as to be a negligible quantity, and the spread from parent to child is in very truth by direct infection.

The Soil.—On the primary constitutional state depends to a certain extent the susceptibility to tuberculosis. On certain unknown bio-chemical characteristics of the tissues depends the growth of the bacillus when once it has obtained an entrance. Of the latter conditions little is known beyond the fact that the bacillus does not grow in an acid medium. Consequently it is rare to find tuberculous disease of the stomach.

It is a moot question whether the children of a tuberculous parent are more liable than others to contract tuberculosis, apart from the risk of direct infection. Evidence has been brought forward by Squire and Maxon King in favour of the view that there is no such predisposition. It is sometimes even supposed that there is an acquired natural immunity, and in favour of this it must be borne in mind that such children are much more exposed to infection than others. The case incidence should be, therefore, much higher. According to Maxon King it is actually lower. The resistance to infection is only a question of degree, and is largely influenced, increased or decreased, by surrounding conditions. Probably all animals can be infected under suitable conditions as to dosage and surroundings. What is true of animals in this connection almost certainly applies equally to children.

The Seed.—According to Möller there are as many as nine acid-resisting bacilli which stain like the tubercle bacillus. Notable among these are the butter bacillus and the smegma bacillus. Care must be taken not to rely upon staining properties as proof that a suspicious bacillus is the tubercle bacillus. The most certain proof is that obtained by the intra-peritoneal inoculation of guinea-pigs.

From the moment of birth the child is liable to infection from many sources. Now I do not suffer from bacillophobia, but if there were no tubercle bacillus there would be no tuberculosis. Yet the bacillus need not be the terrible enemy some of us consider it. Granted that its ravages are great, it does not follow that we are going the best way to eradicate the disease by building sanatoria to keep alive those already infected, enabling them to propagate their species, even in sanatoria; or by passing bye-laws to prevent the homely habit of spitting or the custom of kissing those who are not clean-shaven. Surely this is not the ideal way of attacking a widely prevalent disease. The farmer who wishes to keep thistles out of his land does not set up wind screens to keep out the thistle down. Such an attempt would be as foolish as it would be unavailing. We can, perhaps, diminish to a slight extent the distribution of the tubercle bacillus but, like the farmer, we must devote our energies mainly to tilling the soil effectually, to increasing the resisting power of the individual until he can scoff, as many a healthy man now scoffs, at that arch-fiend the tubercle bacillus. If preventable, why not prevented? The man in the street is governed by phrases and this has caught his ear. How are we to answer him? Gentlemen, the future of the nation is in the hands of little children. The future of the nation is in the hands of our profession, for on us depends the health of the children. Let us increase their powers of resistance to infection and diminish the liability to exposure. If the constitution is sound and the environment as perfect as can be obtained in this imperfect world, then the bacillus becomes a comparatively harmless foe.

The Environment, or Manures.—On the other hand, the strength of the foe is increased by every factor which lowers the health of the child. If in addition there be inherited delicacy or weakness of constitution due to parental tuberculosis, syphilis, alcoholism or mere delicacy, the danger of bad environment is exaggerated. Everything which lowers the health of the child, such as impure air, lack of sunlight, close rooms, unsuitable or insufficient food, imperfect or badly applied clothing, and bad hygienic conditions generally, acts as a predisposing cause of tuberculous disease. So too local or general debility of the tissues may be due to local or general disease or injury and, by lowering the vital resistance, predispose to infection.

Under all these conditions the ubiquitous bacillus may find on entrance a suitable soil for its growth and development in the damaged area of impaired vitality.

But though the seed may enter, and does enter, it does not always acquire a holding and flourish. Sometimes it falls on stony ground. The soil is not always suitable. Thus, clinical evidence favours the view that the uric acid diathesis is resistant to tuberculous infection.

Mode of Infection.—The bacillus enters by the respiratory tract, the alimentary tract, or the cutaneous system. Infection through the skin is rare in adults and still more rare in children. We need not consider it. The aërial convection of tuberculosis has been proved by direct experiment in animals by diffusing dry powdered sputum in the hutches of rabbits. Probably this is the great source of infection in man. The possibility of such infection is great. It has been estimated by Böllinger that one cubic centimetre of sputum may contain a million bacilli. According to Nuttall, as many as 4,000,000,000 may be expectorated in the space of twenty-four hours. Fortunately most of them are dead bacilli. Still it is clear that the neighbourhood of a consumptive, who promiscuously spits about the floor, may be highly infectious. In coughing or speaking loudly bacilli may be mingled with the spray. If the patient uses handkerchiefs these, too, may convey the bacillus, and it may be spread by direct contact with the lips, &c. After puberty, the lungs are almost invariably found affected in cases of tuberculosis. In childhood we also find that either the lungs or some of the thoracic glands are almost always affected. In a paper read before this Society in November of last year on "The Ætiology and Morbid Anatomy of Tuberculous Meningitis" I brought forward evidence to show that the lungs or bronchial glands, or both, were almost invariably affected. In no less than twenty-three out of twenty-five cases, fully examined post-mortem, some one or more of the mediastinal glands were caseous. In the other two none of the glands appeared infected. In four the mesenteric glands were also involved. This evidence I took to be opposed to the view that infection takes place through the aliments. I expect that pathological evidence will be in favour of a similar proposition in the case of tuberculous peritonitis. It is rare for the disease to be limited to the abdominal cavity. On the other hand infection through the lungs is not the simple matter we might regard it, considering the laws of diffusion of gases, the filtering of air through the nose, the ciliary action of the cells lining the trachea, the results of experiments with the inhalation of heavy dust, and the differences in the localisation of the disease in the lungs of adults and children, it might be fairly urged that the bacilli do not reach the lungs through the inspired air, but through some other channel, such as the mucous membrane of the mouth, tonsils, pharynx, &c, *via* the lymphatics and glands of the neck.

Many regard the alimentary tract as the chief channel of entrance of the bacillus. This brings us to the question of tuberculous milk. That there is a good deal in the market is undoubted, though I think the prevalence of tuberculosis in cattle and of tuberculous disease of the udder is exaggerated. It is stated that no less than 30 per cent. of all cows are tuberculous, and that 3 per cent. have tuberculous disease of the udder. I do not believe it, and it is opposed to my experience. Opposed also is the view that tuberculous milk is the great source of infection, I should like to quote Professor Carlo Ruata, of Perugia, who maintains that the milk of tuberculous cows never produces tuberculosis in man; that in adult life primary intestinal tuberculosis does not occur; and that in the first years of life tabes mesenterica, as well as other forms of tuberculosis, are always inherited. Not many will, I think, support this statement in its entirety.

The question of the identity of the human with the bovine bacillus is still a matter of uncertainty, though on the whole the probabilities are strongly in favour of identity, modified by environment.

To the professorial mind of Koch a few experiments with negative results were sufficient justification for stating that the bacilli are different; that the human bacillus will not give rise to bovine tuberculosis; and that the bovine bacillus will not cause tuberculosis in the human subject. From this it is argued that tuberculous milk is harmless and this view is supported by asserting the infrequency of primary intestinal tuberculosis in infancy, and by the absence of wide-spread epidemics due to the milk of tuberculous cows. It is assumed that alimenta can only produce the disease by setting up a primary tuberculosis of the intestine. That such disease is rare is shown by the results of autopsies on tuberculous children. Biedert found primary intestinal disease is only 16 out of 3,104 cases. Baginsky found in 933 cases no such disease, unless the lungs and bronchial glands were also affected.

Many observers have succeeded (Böllinger, Crookshank, Sidney Martin, de Jong, Arloing, Ravenal, Wolff) in showing that the human bacillus will produce tuberculosis in cattle, chiefly by experiments on calves, although it has not the same degree of virulence as the bovine bacillus. In fact the bovine bacillus appears to be more virulent to all animals used for experimental inoculation. Probably Koch's negative results of experimental inoculation were due to using too small doses of insufficient virulence.

Another argument against Koch's views is that it can be shown, by feeding experiments, that tuberculosis may result without the production of a primary lesion. Thus the cervical glands of the pig (Woodhead) and the mesenteric glands of the guinea-pig (Cornil and Babes, Baumgarten, Klebs, &c.) may become tuberculous, although no local evidence of disease can be found. Bacilli have been found in the tonsils with an apparently intact mucous membrane (Dieulafoy, A. Latham). The experimental infection of the nasal mucosa by rubbing on sputa will cause tuberculosis but no local lesion (Cornet, Renshaw). Thus it appears that the bacillus can enter through an intact mucous membrane, *i.e.*, intact to the naked eye. Whether it can pass through a healthy mucosa is a matter of doubt. It is so easy to suppose some local defect of nutrition or vitality to account for it.

Milk is the staple article of diet during the first year or more of life. In the case of hand-fed children it is usually cow's milk, especially among the better classes. There is no doubt that much milk is sold containing the tubercle bacillus. Yet tuberculous lesions in the abdomen are not very common. They are more common among the poor than the rich, although, or perhaps because, the former get less milk. In addition, the milk obtained by the poor is likely to be poorer in quality, cheaper, and perhaps infected, whereas among the better classes more care is taken in obtaining and preparing it. Among the poor all the predisposing factors are much more in evidence, but I can find no indication that a higher percentage of children fed on cow's milk get tuberculous peritonitis than of those fed on condensed milk. I regard the latter as the more susceptible.

The alimentary canal is certainly very insusceptible to infection by the human tubercle bacillus. This is shown by the frequency with which we find no intestinal infection and no caseation of mesenteric glands in infants and young children who have been for weeks or months swallowing sputa from tuberculous cavities in the lungs. Still, the result of autopsies on children at Great Ormond Street, shows that 59 per cent. of tuberculous children have tuberculous mesenteric glands, and that 80 per cent. of cases of tuberculous mesenteric glands showed ulceration of the bowel. From this it follows that 47·2 per cent. of tuberculous children have ulceration of the bowel, a percentage which seems unduly high.

Statistics like this strongly suggest alimentary infection. We ought, indeed, to have large numbers of instances of alimentary infection if tuberculous milk is widely distributed, and if the bovine bacillus is much more virulent than the human variety. There is no reason for assuming that man is an exception to other animals in the degree of susceptibility to infection by the bovine bacillus. Supposing the bacillus to pass through the stomach uninjured, and to be able to pass through the intact mucous membrane of the intestinal tract, two channels are open to it. It may pass into the blood stream and be carried to the liver. If it take this course the liver must have a powerfully destructive effect, for tuberculous foci in the liver are rare, except in the case of an acute general dissemination. Or it may pass by the lymph channels to the glands and be there destroyed, or set up caseation. The glands act as a dam, and should the dam fail or burst, the bacilli may pass onwards into the thoracic duct and so to the blood, giving rise to a general infection.

Assuming that the bacillus reaches the systemic circulation by this course, why is it that the lungs and thoracic glands are the organs commonly infected? The infected blood will be distributed throughout the systemic circulation and, with the exception of that which passes by the bronchial arteries, only reach the lungs after passing through the body and the right side of the heart. The bronchial glands are caseous in 75 to 80 per cent. of tuberculous children. Not all the lymph from the intestines passes through the glands, so it is possible that the lymph stream may be infected and the bacillus may set up tuberculous disease in glands further on, such as the mediastinal, or may pass into the thoracic duct and blood stream without going through a gland.

We have, therefore, to assume that if the bacillus reaches the bronchial glands *via* the intestinal canal it does so by evading the mesenteric glands or by passing into the blood stream, and then for some cause or other being carried to these glands. Much more evidence is required before we shall be justified in accepting such an assumption.

Tubercles may occur in and block small arteries or veins. They may break down and cause general dissemination. Such an explanation might be theoretically true of some cases of tuberculous peritonitis. It is not a wild speculation to suppose that the tuberculous process might extend from a gland to an artery, or that an artery might be directly infected through its vasa brevia, and that on breaking down a dissemination in the parts supplied by that artery might result. So far I have been unable to find clear post-mortem evidence of such limited arterial distribution.

Wide dissemination suggests distribution of the infective agent by the blood stream. Wide dissemination is common in infancy, and is most commonly secondary to caseation of a thoracic gland. Dissemination by the blood stream does not, however, clearly explain the limitation of the spread to the peritoneum. We are driven to the view that, if this be the mode of infection, the bacilli must be simultaneously and equally widely distributed throughout the systemic circulation, but that they are destroyed elsewhere than in the peritoneum. We may note in this connection how rarely tuberculous nodules are found in the skin, and that in acute miliary tuberculosis few tubercles are found except in the lungs, unless the illness is rather prolonged. It is probable that in the healthy peritoneum, as in other tissues, the bacilli are destroyed, but that if the resisting power of this large serous membrane be impaired a tuberculous peritonitis will ensue.

As a parallel to this I would suggest that outbreaks of miliary tuberculosis can occur in the system as a whole, or in portions of it, without causing the death of the child. Just as we get ocular evidence of the recovery of cases in which the peritoneum has been found studded with tubercles, so we have clinical evidence which indicates to me that some of the cases diagnosed as capillary bronchitis, ending in recovery, may have been due to an attack of dissemination of miliary tubercles in the lungs.

Though I am inclined to the view that tuberculous peritonitis is usually due to infection through the blood stream, I regard the caseous form as more commonly due to rupture of a caseous mesenteric gland, or to extension from such a gland, in a somewhat similar manner to the extension from a caseous bronchial gland to the lung. At present we seem hardly justified in stating that the mesenteric glands become caseous as a result of infection from the intestine. It is quite possible that the bacillus is carried to the gland by the blood. Even in advanced cases of tuberculous ulceration of the small and large intestine we do not invariably find caseous mesenteric glands. This was very remarkable in a case I showed before the Medical Society (*Med. Soc. Trans* Vol. xxiv., p. 272). The ulceration was extreme, the glands were not caseous, the peritonitis was limited to the bases of the ulcers, and there was an old tuberculous focus in the apex of one lung. If we get no caseation in the glands in such a case as this, how much less probable is infection of the glands through the mucous membrane of the healthy intestine. In a few instances the peritonitis appears to be secondary to a primary tuberculosis of the genital organs. More often both are secondary.

The predisposing causes which render the peritoneum susceptible are mainly those due to improper feeding, gastro-intestinal disturbance, and general malnutrition. Another factor, very prevalent among the poor, is unsuitable clothing. We constantly see that the ordinary child of the poor is badly clad, with the clothes so arranged as to hang from the shoulders. When the child is lifted up, under the arms as so often happens, the abdomen is seen to be bare, or, at any rate, only protected by a thick layer of dirt. In young children, and in girls for many years, the abdomen is insufficiently protected. Perhaps this is the explanation of the greater frequency of tuberculous peritonitis in females in later life.

Constantly in the early stages of the disease we find a distended belly, flatulence and constipation; a condition we cannot invariably diagnose as incipient tuberculous peritonitis. Such symptoms often, but not invariably, prove tuberculous.

In conclusion, I would suggest that it is not proved that all forms of tuberculous peritonitis are due to the same brand of bacillus. Both clinically and pathologically we seem to have grounds for supposing that the bacillus exerts a different effect according as it is of the human or possibly the bovine species. Certainly, in some instances of chronic tuberculosis in children the character of the spleen closely simulates that seen in the tuberculosis of guinea-pigs The question is one well worthy of patient elucidation.

A special meeting of the South-West London Medical Society is to be held at the Drill Hall, Clapham Junction, on Friday, January 2nd, to consider the course to be pursued in view of the attitude adopted by Mr. Troutbeck the coroner for the district, towards medical practitioners. All members of the profession are invited to be present.

A deputation from the Imperial Vaccination League is to be received by the President of the Local Government Board on January 14th to discuss forthcoming vaccination legislation.

A CASE OF LYMPHADENOMA ASSOCIATED WITH RECURRENT FEVER. (a)

By HENRY T. BEWLEY, M.D.,
Physician to the Adelaide Hospital,
AND
J. ALFRED SCOTT, F.R.C.S.I.,
Pathologist to the Adelaide Hospital, and Professor of Physiology, R.C.S I.

Cases of long-continued pyrexia, not due to any of the ordinary causes—tuberculosis, typhoid, or septicæmia in its usual sense—occasionally occur, and, from their obscurity as well as rarity, deserve some consideration. The case we are about to bring before the Academy presents many cases of interest.

Case.—Mr. H., born in 1865. His mother died of phthisis. He was a man strongly built, and about 5 ft. 8 ins. in height. He went to sea as an engineer on various cargo-steamers, and was in many places where malaria exists, but never had an attack of this disease. He contracted syphilis six or eight years ago, and was treated with mercury; it was a mild attack, and he never had any recurrence of its symptoms. He remained at his work as an engineer till 1898, when he was employed on a grain steamer. Here he was greatly exposed to the dust of the grain while the boat was being loaded and unloaded, and he seems to have suffered in some way from its effects At any rate some of his friends thought he never seemed quite the same man afterwards.

In 1898 he left his work on board ship and became a commercial traveller, travelling mostly in the North of England. His health kept very good till the end of October, 1900. At this time he began to feel poorly; he became disinclined for work, lost his appetite, and developed a cough. He consulted a doctor in Hull, who found his temperature was 101° or 102°, and believed he heard some râles in his right apex. The doctor concluded Mr. H. was developing phthisis, and advised him to go home.

I saw him at his father's house in Ranelagh, on November 11th, 1900. His temperature was raised and he obviously felt very unwell, but I could not detect any physical signs of disease in either lung. In fact there was no sign of illness except the pyrexia. There were no spots; the spleen was not enlarged; his urine was healthy; his pulse quiet, from 66 to 80; his heart sound; his bowels rather confined, so that an occasional dose of cascara or other purgative was needed. He could take light food fairly well. He had some cough, rather paroxysmal in character, and tending to end in retching, and occasionally in vomiting. From the absence of every other obvious cause of fever I began to suspect an anomalous case of typhoid, and Dr. Scott kindly examined his blood for me. He found Widal's reaction present, though not in a very marked degree, so we concluded the disease was typhoid.

The attack lasted four weeks; then, after a week's interval of normal temperature there was a relapse of ten days' duration; then, after ten days, a second slighter relapse of ten days. After this his temperature remained down; he grew stronger: ate largely and grew fat, and went to Llandudno on February 6th, 1901. He remained there for a month and though he became fairly well he never got quite strong, and suffered from cold perspirations, also from pain and tenderness in his feet.

He came home on March 7th, 1901, very fairly well, but soon developed a cold and again became feverish. I again failed to detect any physical sign of any disease. He, however, was more ill than during his first attack, less able to take food, and more depressed. His temperature, the course of which was quite irregular, tended to rise. On April 9th Dr. Little saw him with me, and agreed with me that his organs were healthy. Arguing, however, from the paroxysmal cough, which often ended in retching, he thought there were probably enlarged intra-thoracic glands, either syphilitic or tuberculous, irritating some of the nerves in the thorax, a view which is remarkably borne out by the autopsy.

(a) Read before the Section of Medicine of the Royal Academy of Medicine in Ireland on Friday, November 21st, 1902.

Mr. H. became worse, began to be delirious at night, his temperature was found to be persistently about 103°. Dr. Scott again examined his sputum, urine and blood. The urine was healthy; there was no trace of tubercle or malaria; there were no microbes found in the blood; the blood-count was as follows:—

Red blood corpuscles, 3,570,000 per cm.
1 or 2 white in 2,288.
Hæmoglobin, 90 per cent. = 1 3 normal per red blood corpuscle.

All treatment—quinine, mercury, arsenic—was quite ineffectual. It looked as if he were going to die, when on April 26th his temperature began to fall; fell to normal in three days; never rose again; and in a week he was out in the garden, practically well. His family had nursed him, but on April 25th a nurse came, and the improvement seemed to date from several enemas which she gave him, and which thoroughly cleaned out his bowels.

On May 10th he went to Howth and seemed well, but could only walk a short way owing to numbness and tenderness in his feet, which I thought might be due to slight neuritis.

On May 18th his temperature again began to rise; Dr. Little had suggested a sea voyage, and he now resolved to go to Monte Video, for which place he sailed on May 30th, the temperature being then about 103°.

The fever continued till he left Rio on his way back, about the beginning of July. He came home on July 23rd looking well and stout. He was able to walk three or four miles, but still complained of his feet. He spent a month in co. Wexford with friends, and became very fat—almost 14 stone in weight. He came home on October 9th, but soon became dull, apathetic, disinclined to go out. I saw him again on November 2nd, and found again fairly high fever, with nothing apparent to account for it. He steadily became weaker, took but little food, and as he could not be nursed properly at home, came into the Adelaide on November 18th. From that time on his temperature was from 102° to 104°; his bowels were rather confined; he needed occasional purgatives; the urine contained a trace of albumen. Dr. Scott examined his blood on November 26th and found—

Red blood corpuscles, 3,725,000
White blood corpuscles, 1 in 600.
Hæmoglobin 37·5 per cent. = ½ normal per red blood corpuscle.

Thence he became steadily worse; his pulse became weak and frequent, 100, 120, 140. Rhonchi developed in the bronchial tubes; he became delirious, then comatose, and died, as fever patients die, of heart failure on December 2nd, 1901.

To sum up:—This man came of a tuberculous family; had had mild syphilis about 1895; was quite strong till November, 1900, when a fever commenced which lasted over five weeks, and was followed by two relapses of ten days' duration each. He was well for about six weeks; then (about March 15th) a condition of high fever came on and lasted six weeks, ending by crisis on April 27th. On May 18th pyrexia again came on, lasting till the beginning of July. Then he was well till the beginning of November, when high fever recommenced and lasted four weeks—till his death. During all this time, if we exclude the first attack and the relapses, which were probably due to enteric, no one could discover any cause whatever for his pyrexia.

The post-mortem examination showed that the body was well nourished, although not so stout as he had formerly been. In the thorax a large mass could easily be seen under the sternum, in front of the trachea. This lay over the upper portion of the pericardium, and extended on each side above and behind the roots of both lungs, lying round the œsophagus and behind the heart. Roughly, its dimensions were about four inches wide at the upper part and about five inches long at the back. It was made up of a number of ovoid masses, like large lymphatic glands, about ½ inch to 1½ inches diameter. These when cut appeared of light grey colour, with black spots scattered through them (absorbed carbon). In some cases these latter were absent. A small separate mass of similar appearance, about ½ inch diameter, was attached to the inner pleural surface of the upper lobe of the right lung, extending about half its size into the lung substance. The middle lobe contained a small oval mass ¾ inch long, apparently calcified at the centre.

In the abdominal cavity more of these apparently enlarged glands existed at the attachment of the mesentery round the aorta, and in the mesentery a calcified mass, about one inch long, was found. A small grey spot was noticed on the liver surface. The spleen was enlarged, measuring about 6 inches by 3½ inches, and weighed 1 lb. 2 ozs. The surface was mottled with irregular, light patches, which could be felt to be firm, and which appeared on section to be in the substance of the spleen. Those at the capsule looked like small infarctions.

The intestines were examined through their whole length. Peyer's patches were almost completely absent. In one spot a few follicles were scattered over an area, which was thinner and paler than the surrounding portion, and other oval pale portions could be seen, about the size of a Peyer's patch. These were probably the scars of old typhoid ulcers. No *increase* of the lymphoid tissue was seen.

The heart, brain, kidneys, suprarenals, and thyroid were normal.

Microscopically, the appearances of the thoracic tumours and the growths in the liver and spleen were very similar. Those in the thorax are principally composed of fibrous tissue strands, with a few cells lying between them. Most of the cells are small, similar to lymph cells, with a few larger ones, some of which have apparently more than one nucleus. In the spleen the fibres were finer, but otherwise the general description was the same.

The appearances agree with those described by Greenfield (*Path. Soc. Jour*, 1878, xxix., p. 272) as found in some cases of lymphadenoma, and is apparently the same condition called by Virchow lympho-sarcoma. There are two extreme forms found in this disease. In the majority of cases they appear to be simply enlarged glands with, perhaps, an apparent removal of the normal structure by an overgrowth of cells. In other cases—whether a later one or not it is difficult to determine—there is an overgrowth of the connective tissue fibres, with an inverse reduction in the number of lymph cells, together with the presence of multinucleated cells, possibly endolithial. Occasionally the arrangement of the cells suggests the appearances seen in some sarcomata, which is emphasised by the tendency of these tumours to form metastatic growths in other organs. The growths at present under consideration apparently belong to those cases associated with an increase of the connective tissue, the appearance being very like those figured by Greenfield.

Sections from various portions were examined for micro-organisms, none being found. I thought some would have been there from the history of steamer dust. While it is possible that such may be present which cannot be stained by present methods, it is also conceivable that they may have been a factor in the case at an early stage and have vanished subsequently. This, indeed, has been noticed, in a case quoted, by Shaw (*Edinburgh Medical Journal*, December, 1901), to which our attention was directed by Dr. Little, and has been of great use. None were found in this case, when the blood was examined during one of the febrile attacks. Might it not be possible that such were inhaled a couple of years ago when on the grain steamer, and that these micro-organisms started some interstitial inflammation which continued to increase although the actual cause was removed? There was no leucocytosis on either of the occasions when the blood was examined, a result which is not surprising in the light of the post-mortem examination, so many of the lymph glands being reduced to simple masses of fibrous tissue.

It is difficult to discuss the question of the intermittent high temperature; nothing was seen which would give any reason for it. Micro-organisms have been seen in published cases coinciding with the periods of high temperature, but not in this case.

The temperature appears to be generally higher than normal in Hodgkin's disease, though not always intermittent. In these cases it has been suggested that the high temperature coincides with the period of active growth of the tumours where such do not grow quite regularly.

Which of these two views is correct? Do some cases of lymphadenoma form in their growth some poison which causes fever? or are the attacks of fever due to the more or less accidental entrance into the body of microbes? To these questions it is not yet possible to give any definite answer. Dr. Shaw (*loc. cit.*) favours the latter view. The closing sentence of his paper will express much of what is known on this obscure subject. He writes: "Consideration of the above cases impresses the view that 'lymphadenoma with recurrent fever' is not a special form of disease; that such cases are due to a terminal infection occurring at any time during the last year of life of some patients affected with lymphadenoma; that the nature of the bacterial invasion is different in different cases; and that in some cases proof of a bacterial invasion is wanting; that in a considerable number of cases of lymphadenoma with recurrent fever there is a great constitutional disturbance with elevation of temperature, rigors, vomiting and diarrhœa, anorexia and malaise; that in some cases urobilinurea is a marked symptom; that in some of the cases the superficial lymphatic glands and even the spleen became very tender and enlarged during the attacks; and that the skin over the enlarged glands may become reddened and show increase of local temperature. Finally, that the prognosis in such cases is, as a rule, hopeless, and that the duration of life after the onset of the periodic attacks of fever averages about seven and a half months, but may be as much as twelve or fourteen months."

ON FOUR CASES OF PERFORATING GASTRIC ULCER OPERATED UPON, WITH THREE RECOVERIES.

By ROBERT JONES, F.R.C.S.E,
Hon. Surgeon, Royal Southern Hospital, Liverpool, &c.

Three of the operations which I report occurred in the hospital. My first took place outside, and I include it in this report in order to emphasise the great advantage of operating at once.

The patient was a girl, æt. 19, well developed, and exhibiting no obvious signs of anæmia. She was a shop-girl, and had been accustomed to long hours and hurried meals. When nine years old she had been treated for a tuberculous elbow, and later for a tuberculous dactylitis. For the last seven years she had enjoyed the best of health. Until a fortnight previously to her present illness, apart from a very occasional dyspepsia, generally due to some dietetic indiscretion, she had exhibited no signs of ulcer. She admitted being treated for palpitation two years before, and that she had been ordered to take iron pills.

A fortnight before I saw her she had returned from her summer holiday, and after an attack of sea-sickness had complained of pain after every meal. From its severity, the ease with which it could be localised, and the tenderness on pressure, the doctor diagnosed a gastric ulcer, and gave full instructions as to diet. A few days later the urgent symptoms arose, and Dr. Bennett hurriedly attended. He found the girl in very great pain, extremely tender over the abdomen, with rapid pulse and drawn face. I was sent for, and in less than three hours after the onset of acute symptoms the operation was begun. A median incision was employed, and the stomach explored, when a small opening was found about large enough to admit a crow-quill. Through this some food had travelled, consisting of partially digested milk. There were no adhesions and barely any signs of even local peritonitis; a little lymph surrounded the orifice, which could be removed with the finger. The edges of the ulcer were not indurated. There had been some escape of gas into the abdomen. The ulcer was situated on the anterior surface of the stomach, a little below the lesser curvature, and quite at the pyloric end. There was nothing, therefore, to prevent a rapid inversion of the ulcer; and having roughened the parts around, a row of Lembert sutures completed the occlusion. The abdomen was irrigated, and the wound was closed without drainage. The patient vomited twice during the night and complained of great pain over the abdomen, and the temperature the following day was 101° and the pulse 115. Two days after the operation there was no pain, the tongue was moist, the pulse 96, the temperature normal, and the patient evinced but little desire for food or water.

On the third day she was fed on small quantities of peptonised milk, which gave her no inconvenience. In three weeks after the operation she was sitting up; and in seven weeks, having taken fourteen days' holiday, she resumed her work. Nearly three years have passed since the operation, and I have every reason to believe she is still well.

The operation lasted less than twenty minutes, and every circumstance favoured her recovery.

The small size of the perforation, the absence of induration, the condition of the surrounding peritoneum, the site of the ulcer, the small quantity and character of the escaped contents, and the fact that only three hours had elapsed since the rupture all rendered the prognosis good and the operation easy. From a study of the girl's history, and the appearance of the ulcer, the possibility of a tuberculous origin is worthy of note.

The second case was sent to me at the Royal Southern Hospital, on November 12th, 1898, by Dr. Humphreys, who had diagnosed a perforation. The patient was a woman, æt. 21. Thirteen hours previous to admission she had been seized with violent abdominal pain and vomiting. I was in the hospital when she was admitted at three o'clock. She looked very distressed, and complained of great thirst, and suffered intense abdominal pain. The pulse was 120, very weak, but not running in character. Her extremities were cold and the abdominal muscles very rigid. A rub could be heard accompanying respiratory movements over left lower ribs in front.

We decided to operate at once, and I wish to acknowledge the help of my colleague, Dr. Alexander. On opening the abdominal cavity, the surface of the colon and stomach were seen to be coated with lymph and to have become adherent to the lower surface of the liver. Adhesions had also formed between the stomach and the abdominal wall. These adhesions were carefully separated, revealing behind a cavity from which oozed brown fluid containing partially digested food. The opening from which this came was found high up beneath the liver, on the anterior surface, nearer the cardiac than the pyloric end. There was considerable difficulty experienced in bringing the ulcer sufficiently to the surface to enable us to stitch. The perforation would about admit a small finger. It was indurated and surrounded by lymph, which was firm and adherent, and was carefully removed by a Volkmann spoon. We then proceeded to introduce sutures, but found they immediately tore through. A silk suture was therefore passed as near the interior of the stomach as we felt to be safe, and made to surround the gastric opening. This was tightened in purse-string fashion and leakage prevented. The wall of the stomach was further brought over it and fixed by a row of Lembert sutures, while this was further fortified by sewing omentum over the region of the ulcer. The operation area was carefully irrigated with saline solution, and a gauze drain inserted. The patient seemed to bear the operation without material increase of shock, and saline injections per rectum were given for the dual purpose of restoring vitality and allaying thirst. On the next and succeeding days she was starved, with the exception of a drachm of water every hour and enemata of brandy, peptonised meat and milk.

On admission her temperature was 100°, and for the first four days it did not rise. Towards the end of the fifth day it fluctuated, its highest point being 101°.

From this time to the fourteenth day it often reached 102°, but the patient in all other respects, save a rapid pulse, seemed fairly well. On the eighth day the drain, which had become adherent, was removed. My house-surgeon, Dr. Owen, to whom I am indebted, noted on the fourteenth day:—"Patient after the operation progressed favourably up to last night, although throughout the fourteen days the breathing was a little rapid. She was, however, able to take bread and a fair amount of beef-tea, milk, &c., and had not vomited since operation. The temperature for the last week had reached 102° in the evening."

She had no rigors.

At 3 a.m., fourteen days after operation, she suddenly developed a ticklish cough, and soon expectorated a quantity of foul-smelling pus. Her breathing became rapid, and at 6 a.m. she looked cyanosed. I was away from home, but Dr. Alexander was fortunately at hand, and at ten o'clock the patient was anæsthetised and the old sinus explored. There was no collection of pus found. An exploring needle was put into the thorax, but only clear fluid withdrawn. The needle was next passed into the left hypochondrium, and pus withdrawn; this was followed by a free incision, giving exit to a quantity of fœtid pus. The cavity was well washed out. The patient was throughout the proceedings very collapsed, and various restoratives were prescribed, including strychnine, digitalin, saline solution, brandy enemata, and sinapism to præcordium. At noon she had sufficiently rallied to inspire hope. In the evening she died.

A post-mortem examination was made by Dr. Owen and Dr. Humphreys. They report that the sinus, which was left at the top of the original laparotomy wound, did not lead to any collection of pus. The upper surface of the liver was adherent to the lower surface of the diaphragm by very firm adhesions. The repair of the stomach performed fourteen days before was seen to be healed and the occlusion complete. The abscess cavity, which was opened the day of the patient's death, was seen to lead towards the posterior part of the under surface of the diaphragm. On separating the left lung from the diaphragm, to which it was firmly fixed, a small hole was found entering lung tissue and perforating diaphragm, and discharging foul-smelling pus. A probe passed through this perforation entered the abscess cavity, explored the previous day by my colleague. On slitting up the walls of this cavity, it was seen to be bounded by the under surface of the diaphragm above and externally; by the colon, stomach, and thickened neighbouring tissues below: its posterior part was the opening communicating with the left lung. The spleen was contained in the centre of this abscess cavity. On opening the chest, some clear serum and lymph were found in the left pleural cavity, and several pleuritic adhesions were apparent. On distending the stomach, no fluid escaped. The wound in the viscus had quite healed, but four of the silk sutures were in situ; the others had disappeared. On the mucous surface a small depression showed where the ulcer had existed. There was no ulcer on the posterior surface.

My third case I saw late at night in consultation with Dr. Fisher, of Sheil Road. The patient, a clerk, with a dyspeptic history, was dining in a café when he was seized with excruciating pain, and fell on the floor writhing in agony. He vomited soon after the onset. A medical man saw him, prescribed morphia and sent him home, where he remained for some hours until Dr. Fisher was called. He stated that his stomach had troubled him for two years, chiefly by way of pain of a burning kind. On one occasion there had been hæmatemesis. Pressure over the stomach always gave him discomfort. Pain generally came on before food, and was usually eased when food was taken. Five or six weeks ago the pain was more constant and more severe, and was localised to the epigastric region. He was fragile, emaciated, and anæmic.

I saw him twelve hours after the onset, and found him lying in bed, having several times vomited. His face was drawn, his pulse 110 and very compressible. There was only a suggestion of distension. The liver dulness was notably diminished, and slightly marked rigidity of the abdomen, absence of abdominal respiration and marked shock.

The history and symptoms pointed to perforation, and two hours later, or fourteen hours after the onset, we operated upon him in the hospital.

The anterior aspect of the stomach was explored, when an opening was found about three inches from the pylorus. Some undigested matter had escaped into the abdomen, and some was noticed issuing from the orifice. Around the opening, which was with difficulty brought to the surface, a considerable lymph exudate was noted, which was carefully removed before dealing with the ulcer. The edges of the ulcer were freshened, inverted and occluded by a double row of Lembert sutures, and some omentum was stitched over the omentum line. Care was taken not to douche the abdomen, and the stomach exudate was merely mopped up by dry aseptic dabs.

The operation, which lasted half an hour, left the patient very collapsed, and we had recourse to hot cloths and strychnine. The patient made an uneventful but slow recovery, now and again vomiting, and once ridding himself of a lemon pip.

The treatment consisted of saline cloths to relieve thirst, alcoholic nutrient enemata, morphia under the skin, and every four hours a teaspoonful of iced water. Feeding by the stomach was very cautiously begun on the fourth day. The patient at this date, eighteen months after the operation, is very fit, having become stout and strong, with barely any dyspeptic trouble.

My last case—a woman of thirty—had been an inmate of the hospital under the care of my colleague, Dr. William Williams. She had been treated for gastric ulcer, and had so far improved that she was allowed to go out. Some weeks later she experienced sudden pain in the abdomen, accompanied by a faintness, retching, but no vomiting. In seven or eight hours she reached the hospital, and an hour later she was on the operating table. Her abdomen was tense and rigid, her liver dulness decreased, her breathing thoracic, with moderate collapse.

On examining the stomach a clean punched-out opening was noted on the anterior aspect, from which issued a thick milky fluid. The opening was grasped by two forceps and drawn up into the wound; this prevented the escape of fluid. A purse-string suture was introduced around the opening nearly half an inch from the edges, and with the two forceps to the outside of the suture ring, the stomach was held while the forceps holding the edges of the wound were depressed and the edges inverted. The circular suture was now made tense and the operation completed by a row of continuous Lembert sutures. No water was introduced into the abdominal cavity, which was hurriedly cleansed by aseptic dry dabs.

The patient made an uninterrupted recovery, and is now, eight months after operation, fat and well, and working.

A greater contrast than that between my first two cases could hardly be found. The first was as simple as the second was complex. The fact that operation was not performed for fourteen hours after perforation was itself sufficient to decide the issue. The adhesions and the involvement of the cardiac end, fixed as it is, rendered suturing a matter of considerable difficulty.

Both my last cases are very encouraging, the third inasmuch as operation was not performed until fourteen hours after the ulcer had opened. Fortunately, but very slight oozing of foodstuff had occurred. In my last case, although leakage had occurred, the character of the stomach contents did not appear to be of a very irritative kind.

It is interesting to note that over 95 per cent. of cases unoperated upon die. Life is rarely prolonged over twenty-four hours. Ulcers are more frequent on the posterior than the anterior surface of the stomach, but perforations are much more frequent on the anterior aspect. This is probably due to the greater facility with which buttressing adhesions form behind. In thirty-one cases operated upon, collected by Barling, twenty-two were on the anterior surface, five on the posterior; subsequent cases confirm this proportion.

What was the cause of this perisplenic and subphrenic abscess not connected with the wound area? Had we found an ulcer on the posterior aspect it would have explained much; but it is noteworthy that cases are recorded where retrogastric and perisplenic abscess have caused death where perforation has occurred on the anterior surface alone. This may be accounted for in one of two ways—either by direct trickling of septic material through the foramen of Winslow into the lesser peritoneal cavity or by lymphatic absorption. In an ulcer on the anterior surface, the gastric contents have but to travel round the right free border of the lesser omentum, and both the greater and lesser peritoneal cavities are soiled; and if the foramen of Winslow be closed by adhesions, the invasion of an abscess in the lesser cavity will be obstructed. This raises a final question, suggested recently by Willoughby Turner, of Brighton. Would it not be wise both to examine the posterior surface of the stomach and, if necessary, to cleanse the lesser peritoneal cavity, which can easily be effected through the layers of the great omentum, or of the transverse meso-colon? The mere irrigation of the greater cavity may be the very means of infecting by septic articles the lesser one; and a survey of reported cases convinces me that, where practicable, irrigation of the greater cavity should not be done. I think it is more advisable to use dry dabs than to dilute, disseminate, and make more soluble the toxic contents. I did not use a drainage-tube in any of my cases.

Mr. Tobin, of Dublin, raises a very interesting question when he pleads that no case of perforated gastric ulcer should be removed from where the lesion has occurred. To anyone who has noted the effect of movement on the escape of the stomach contents, the plea has much to recommend it, and if the diagnosis be correct, the simplest appliances are only needed. Boiled towels, cocaine, a few forceps, domestic needles and thread are all the real requirements in the average case. Many a life has been lost in transit from home to hospital.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

Meeting held Friday, Dec. 19th, 1902.

Dr. C. M. **O'Brien** read a paper on his

EXPERIENCES OF A YEAR'S TRIAL OF THE FINSEN TREATMENT FOR LUPUS,

exhibiting a number of patients already subjected to the method, with short descriptive histories. The cases presented great variety in extent, character, and duration, which varied from two to twenty-eight years. The cure of some and improvement of all attended his efforts, while the cure of others appeared to him to be merely a matter of time. As regards permanency of cure he was of the opinion that the method was entitled to a premier place in this respect. This opinion he formed from personal examination of many cases at the Finsen Institute, Copenhagen, that were cured and remained so from one to six years. He gave a demonstration of the lamp and its method of application, and said that most of the objections hitherto complained of in the use of the French lamp as compared with the Finsen lamp could be obviated by prolonging the duration of each sitting, while at the same time increasing the intensity of the light. The reactions were in all cases better, and penetration to the deeper tissues more manifest.

Dr. **Walter Smith** said that as regarded test of cure naked-eye inspection was not sufficient. His method was to press blood away from the part with a watch glass, and see whether any characteristic brown nodules were still left in the skin. There were different methods of treatment: 1. Excision. He thought that this, combined with careful suturing, gave good results in suitable cases. 2. Caustic treatment, which he did not consider a good one. 3. Radiant energy treatment, of which the Finsen light was a form. The Finsen rays might be defined as filtered light, as only the violet end of the spectrum is used. The action of the light was conditioned by the body on which it fell. In the therapeutic contrast between Finsen rays and X-rays, the latter appeared to have a much more stimulant effect on nutrition of skin than Finsen rays. The X-rays will promote growth of hair, but if pushed too far will produce a depilatory effect.

Sir **George Duffy** said that in his hospital they had used the Finsen light since April last, and had had a number of cases which were more or less successful. As regarded cosmetic effect it seemed to be extremely useful in some cases, in other cases the disease was entirely arrested. He had used certain applications in conjunction with the light treatment when the disease was spread over too large surface for the lamp to cover at once, such as a weak ointment made with pyrogallic acid. He had sittings of fifteen minutes, and even this he sometimes found too long. Some cases reacted more than others. The scar left was more pliable and softer than that resulting from any other treatment.

Dr. **Watson** said he had treated about twenty cases of skin disease with X-rays. He used the ordinary apparatus, covering up all the sound tissues with lead foil. It was mostly used in those cases of lupus which had refused operation, but those cases which had been previously scraped reacted quicker and better.

Dr. **Kirkpatrick** had seen a good many cases of lupus treated by scraping, and he thought the reason that this treatment had fallen into disrepute was that patients expected to be cured by one operation, whereas it needed frequent repetition.

Dr. **O'Brien**, in replying, said that a surgeon could not completely remove the disease. The light treatment would cure completely if it were given sufficient time. As regarded difference between X-rays and Finsen light, the ultra-violet rays were supposed to be bactericidal. With regard to applications Finsen used a 6 per cent. pyrogallic acid ointment along with the light, to give better transmission with beneficial results. His experience was that fifteen minutes' sitting gave scarcely any reaction, and he had prolonged sittings to an hour and ten minutes.

Dr. **Joseph O'Carroll** recorded a case of

PAROXYSMAL TACHYCARDIA

which came under his notice in the Whitworth Hospital, Dublin, in July, 1901. The patient was a governess, unmarried, æt. 34, who fourteen years previously began to suffer from attacks of violent sub-sternal pain accompanied by rapid cardiac action. These attacks, occasional at first, gradually grew more frequent, till in 1900 they had increased to about five per week. In duration they varied from a few minutes to a few hours. Their onset was preceded by dimness of vision, sometimes amounting to almost complete blindness. Tachycardia was a constant accompaniment of the pain, the heart's rate on some occasions reaching 260 beats per minute. An attack would end by a brief but violent exacerbation of pain and a subjective sensation of something shifting from left to right in the thorax. Many lines of treatment were tried in vain till finally Dr. O'Carroll administered bromide in gradually increasing doses, when, *post hoc* or *propter hoc*, the paroxysms of pain and heart hurry improved so much that it is now six months since the last attack. The author suggested the possibility of this case being one of "visceral epilepsy."

Professor Thompson, Dr. Leeper, Dr. Travers Smith and Dr. Walter Smith spoke.

HARVEIAN SOCIETY OF LONDON.

Meeting held December 18th, 1902.

Mr. Watson Cheyne, C.B., F.R.S., the President, in the Chair.

Clinical Evening.

Dr. A. **Morison** exhibited a child five months old who showed the dilated veins which a French author described as "venous dystrophy," and attributed to specific disease. Dr. Morison could find no evidence of specific disease in the case exhibited, and ascribed the malnutrition of the child and the increased intercranial pressure to over-production of children by a delicate mother rather than to specific disease.

Dr. **Wilfrid Harris** showed a woman, æt. 24, who suffered with a sore throat, not diagnosed as diphtheria at the time, January, 1900. A few weeks later she had difficulty in swallowing, and nasal regurgitation with altered voice. Later on the muscles of the eyes and lips became affected. In November, 1901, she was treated by hypodermic injections of strychnine, but she became worse. Her present state.—There is complete paralysis for reflex and voluntary movement of the palate, bilateral wasting and almost complete paralysis of the orbicularis palpebrarum, and less marked in the orbicularis oris. Tongue partially atrophied and weak. Sensation diminished on pharynx. Deep reflexes all brisk, plantar reflexes could not be obtained. Electrical reaction very slight to strong Faradism in soft palate with well-marked reaction to galvanism, K > A. Very slight reaction to Faradism in orbicularis palpebrarum, with better marked reaction to galvanism K > A. Under treatment with galvanism of affected muscles for five months, and with iodide of potassium in ten to fifteen grain doses three times a day, the condition had scarcely altered.

Dr. **Risien Russell** showed a case of peripheral neuritis with paralysis of the right side of the face of peripheral type, paralysis of the right external rectus, slight paresis of the left external rectus, and well-marked double optic neuritis subsiding into atrophy. Under treatment the paralysis of the face and of the external recti had recovered, and the limbs were also improving, though the patient was still unable to walk or stand. No cause had been determined, but the appearance of the patient and the features of the paralysis of the limbs made alcohol most probable.

Dr. G. **Cautley** showed, for Mr. P. L. Daniel, a woman, æt. 63, on whom resection of the supraorbital nerve had been performed for severe neuralgia. The pain followed a bad attack of herpes in the region supplied by this nerve, and was accompanied by marked trophic changes in the skin and hair, affecting also the blood vessels. Medical treatment proved useless. There is an extensive scar on the right side of the forehead and right eyebrow with lachrymation and blepharospasmus, loss of hair, and considerable thickening of the scar of a keloid nature, with vascular maculæ. At the operation two nerves were found, and about half an inch excised. The blood vessels were much compressed. The operation had done no marked good to the pain, but the nutrition of the affected parts had somewhat improved.

Mr. **Jaffrey** said he had seen marked improvement in certain cases of severe trigeminal neuralgia by the injection of osmic (a) acid into the affected nerve. In a case of his own, where the third division of the fifth nerve was affected, he trephined the ramus of the lower jaw and injected osmic acid into the inferior dental and gustatory nerves with complete success.

The cases were also discussed by Mr. Campbell Williams and Dr. G. H. Barton.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Meeting at Manchester, Friday, December 19th, 1902, Dr. S. **Buckley**, President, in the Chair.

Dr. **Lloyd Roberts** (Manchester) showed a specimen of a

PAPILLIFEROUS CYSTADENOMA REMOVED FROM THE ABDOMINAL WALL FOURTEEN YEARS AFTER OVARIOTOMY.

The patient, æt. 48, married, 7-para, last child born four years ago, had noticed a lump in the abdomen for about six months. It was steadily increasing. The left ovary had been removed for cystic tumour about fourteen years before. The tumour was felt just to the left of the cicatrix left by the former operation. It was attached to the abdominal wall, but fully movable otherwise. It felt hardish, but resonance was only slightly diminished over its surface. The abdomen was opened and about three pints of ascitic fluid escaped. The tumour was found to be attached to the cicatrix, and was intimately connected with the parietal peritoneum. Some coils of intestine adhered to the under surface and required separation. The cyst was carefully detached and removed. There was no pedicle. The right ovary was healthy, and there was no trace of the left ovary which had been removed fourteen years before. The patient recovered. The specimen was described as a papilliferous cystadenoma of the subperitoneal tissues of the abdominal wall. The structure closely resembling that commonly occurring in the ovary, suggests that the growth is secondary to the ovarian tumour previously removed.

Dr. S. **Buckley** (Manchester) showed a large fibromyoma and cystic ovaries removed by abdominal section. The operation was undertaken in consequence of the severe pain, especially on the left side, which had existed for two or three years. There had recently been an increased menstrual flow, but this increase had not been sufficient to interfere with nutrition. When the abdomen was opened a large fibroid was found attached by a short, broad pedicle to the fundus uteri. This was removed by myomectomy, as were also two smaller fibroids from the anterior surface of the uterus. The ovaries were found cystic and enlarged to the size of large walnuts. They were adherent and wedged between the tumour and the uterus, and, after separation, were removed, together with the tubes. It is probable that the severe pain had been chiefly due to the adherent condition of the ovaries and to their compression by the growth. The patient recovered well and was free from pain.

Dr. W. **Walter** (Manchester) showed a solid ovarian tumour removed from a patient, æt. 58. The swelling had been noticed about three years, but during the last twelve months it had increased more rapidly, and the presence of ascites had become obvious. There was no loss of flesh or cachexia, but the patient's three sisters had suffered from abdominal tumours. The tumour had a short pedicle, and was so closely adherent to the back of the uterus that the signs were those of a uterine rather than of an ovarian tumour. The ascitic fluid was reddish, and amounted to about two pints. The other ovary was cystic, and contained a small fibroid nodule. The microscopical sections showed the growth to be a simple fibroma with commencing myxomatous degeneration. The patient made a good recovery. The question of diagnosis and prognosis in solid ovarian tumours was discussed.

Dr. **Walter** also showed an ovarian cyst with twisted pedicle. The tumour had been known to be present for some time, but rapidly increased in size after an injury. Sections of the cyst showed interstitial hæmorrhage which had separated the layers of the wall.

Dr. H. **Briggs** (Liverpool) showed (1) a small ovarian cyst (2¼ by 4¼ ins.) associated with metrostaxis and retro-uterine hæmorrhage. The source of the bleeding was not obvious, but there was no possible evidence of extra uterine gestation. (2) Fundal fibroid polypus and inverted uterus. The uterus and growth had been successfully removed by vaginal hysterectomy. The patient having passed the menopause no attempt was made to save the uterus. Reposition of the uterus after removal of the polypus would no doubt have been impossible. (3) Early cancer of the cervix uteri, with questions as to the early symptoms of the disease.

Dr. **Arnold W. W. Lea** (Manchester) related a case of acute prolapus of the urethra. Owing to the œdematous and strangulated condition of the prolapsed mass it was found necessary to resect this part of the urethral mucous membrane. The result was completely satisfactory.

The cause of the condition was discussed but was not definitely explained. There was a little cystitis, but this was probably not present before the attack. Masturbation was suspected as a possible cause.

The papers were discussed by Drs. W. Walter, H. Briggs, T. B. Grimsdall, W. E. Fothergill, A. Donald, Lloyd Roberts, E. T. Davies, and Mr. Stanmore Bishop.

Divergent Opinions on Appendicitis.

M. Championnière spoke at the last meeting of the Société de Chirurgie on the divergence of views among his colleagues on the treatment of appendicitis. They were divided into operations *à froid* and operations *a chaud*. For his part he was extremely struck at the beginning by the frequency of errors in the diagnosis which caused patients to be operated on who were not suffering from appendicitis. But at present he believed that such errors were rare, as the method of diagnosis was very much perfected. On the other hand, he was convinced of the frequent impossibility of foreseeing what might become of appendicitis, and of the necessity of operating, even at the risk of committing an error, in orderthat a patient should not be left to die when an early operation might save. Out of a series of forty-four patients operated on by him during the suppurative period he had twelve deaths; of the remainder several presented lesions of such gravity that they would have succumbed if he had not operated.

As to the dangers of purgatives, which had been so much insisted on by many of his colleagues, he was not entirely convinced, and in that he was upheld by the opinion of his American *confrères*. On the other hand, he considered that opium was extremely dangerous; the gravest cases he had to deal with were those which had been treated at the outset with opium internally and the ice-bag externally. He thought even that in many cases it was the opium itself which had provoked the appendicitis, for he had seen patients operated on who had no trace at the beginning of appendicitis, and who had been submitted wrongfully to the opium treatment.

The divergences of opinion which divided his colleagues were derived in great part from the fact that they did not make the same diagnosis in a large number of cases, and the administration of opium was a potent cause of those differences of opinion: it masked a certain number of symptoms, as well as the clinical evolution of the affection.

It may be remarked here that the speaker who so strongly denounced the classical medical treatment failed to indicate what was the medical treatment which met his approbation. Have we not all, over and over again, had the satisfaction of arresting in its inception appendicitis by the application of ice and the administration of opium internally? To what cases are reserved the operations *a froid*, which, by the way, are by far the most numerous, if not those which had been treated medically during the inflammatory period?

It is true that some surgeons have advocated the application of belladonna and mercurial ointment and poultices, but it is doubtful if the advantage over the classical treatment is sufficient to exclude the latter so completely.

Treatment of Neuralgia.

At the meeting of the Société Médicale, M. Marie related the results he obtained in a certain number of cases of neuralgia from subcutaneous injections of air, as recommended by M. Cordier, of Lyons. The treatment consists in injecting over the seat of pain half a litre of filtered air. In several cases of sciatica, in one case of zona, the pain disappeared immediately. The speaker attributed the good effects of the injections to a kind of extension of the nerve extremities, and also to the formation of an air cushion, which protected the extremities against any external pressure.

M. Chauffard said that for a patient suffering from a pleuritic stitch which had resisted every treatment he recommended an injection of air. The result was immediate; the pain disappeared as soon as the air was injected under the skin.

Berlin, December 27th, 1902.

At the Medical Society Hr. König gave an address on

Operation without Direct Contact with the Wound.

On bacteriological grounds the basic principle was, even before the commencement of the operation, to disinfect everything that came into contact with the wound, the most powerful of disinfectants being heat. Everything pertaining to the operation could be made germ free only in a bacteriological sense, and this was so with the patient's body, but in regard to a most important object, the hand of the surgeon, especially the part under the nails; this had not yet been possible. It could, indeed, be better done with one man than with another; better when the nail grew parallel with the end phalanx, less so when it grew curved over it. Washing in hot water from 40° to 50° C. for ten minutes was the safest method of disinfecting the hands, but this could not be borne by everybody. To this he added the disinfection proposed by Fürbringer.

If we could not disinfect our hands thoroughly there was danger of causing infection, especially in the case of operations on joints and cavities. The uncertainty attending operations in such localities must have led to the thought of avoiding all direct contact with the wounded surface with the fingers. We could not quite dispense with the hand in all operations, but in some it could be done with some little trouble, as in simple extirpation of the appendix *a froid*. If we had to hold back the soft parts, they could first be covered with layers of sterile gauze.

What a large percentage of operations could be performed without contact was shown by the fact that of the last 1,000 performed at the Charité more than 600 were of this category, and amongst them more than 100 operations on joints which recovered without the least disturbance.

The instrumentarium was the usual, except that the forceps all had long handles. The Americal ball forceps were useful. One could even easily learn to apply ligatures without touching the wound with the fingers.

As examples of fingerless operations he mentioned osteotomy in genu valgum and the extirpation of the meniscus in the knee-joint. The greatest success of the method, however, lay in the bloody treatment of fracture of joints, which could be attacked with full certainty. He believed that the adoption of this method would be a blessing to humanity.

Hr. Liebreich then gave an address on

The Action of Borax and Boracic Acid.

He pointed out the danger of having certain things prohibited before their harmfulness was sufficiently proved, as scientific attention was drawn from them and fresh things were sought for. Industries were injured thereby and, not least, the people's food. Boracic acid had been held to be harmless for years. No one suspected that even when consumed in excess it had ever done any serious harm. In England and in other countries it had been decided not to forbid its retention. As regarded borax it had been objected that it prevented food being used up properly. If this were so the nitrogenous constituents of the stools would be increased: this was not the case, however. Then it was believed that borax would be eliminated from the system only very slowly. If that were so there would be no danger in it; as a matter of fact, however, the excretion was completed in a few days. Others asserted that borax caused diarrhœa. But if diarrhœa were set up in rabbits it was because too much water was given. In dogs the stools were neither more copious nor more frequent. Then it was said that borax caused vomiting and headache. This was correct only in so far as when large doses were taken on an empty stomach nausea and even vomiting might follow. It was quite a different thing, however, when a small quantity was added to the food. Intravenous injections of considerable quantities of boracic acid did not injure the kidneys in the least: on the contrary, boracic acid could be given with advantage in kidney disease.

He then discussed two deaths said to have followed the use of borax. One patient had serious cardiac disease, the other softening of the brain.

Hoffmann, of Leipsic, added boric acid to fish water and found that with a 0·25 per cent. solution the fish died in a few days. But with an addition of 0·05 per cent. of vinegar they only lived four hours, and with 0·25 per cent. of citric acid only an hour and a half. No one, however, would say from this that vinegar and citric acid were poisonous. He thought it was a pity that from insufficient and one-sided experiments the governing bodies had been led astray to pass wide-reaching regulations.

Hr. von Bergmann defended the governing bodies from reproach, as if they had passed regulations without sufficient motives.

Hr. Liebreich had not reproached the law-giving bodies. He had only attacked the pronounced opinions of the officials of the Reichsgesund Leitamt, upon which the governing bodies acted.

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, December 27th, 1902.

Mitral Insufficiency.

Reiter presented a case to the "Gesellschaft für innere Medizin" which gave rise to a considerable amount of speculation as to how the sound was produced in mitral insufficiency with a loud musical murmur audible to the patient himself. The history, according to the patient's own account, commenced about four years ago with much coughing, dyspnœa, and palpitation, followed, about a year and a half ago, by a singing noise in the chest. The objective observation defined it as fairly regular, and of a loud, high pitch. Similar sounds are to be met with in tendon deposits with fine trellis threadwork.

Chiari some time ago showed pathological specimens of embryonical inhibition of the cardiac valves, to which he attributed the cause of many of these cardiac musical murmurs. Schrötter, on the other hand, gave similar evidence of malformations associated with endocarditis, examples of which he exhibited, with bicuspid insufficiency. Ritter also showed an anatomical preparation of the heart, in which the left ventricle was crossed by a thin tendrous thread, and which, according to Schrötter's clinical observation, had given a high musical tone during life.

Atrophic Paralysis of the Left Arm.

Weinberger then gave a demonstration from a case of atrophic paralysis in the left arm, with ill-defined localisation. The history of the case runs back to about nine years ago, when intense pain in the left arm, followed by emaciation and paralysis, caused the patient to lie for months in bed. This illness, according to his own account, kept him at home for a year, after which the paralysis began to disappear, and bulk increased. He improved so rapidly as to be able to resume work as a labourer, which he continued till 1898, or four years ago, when he became ill again and was confined for six weeks in bed with the same phenomena that had occurred five years previously. About the end of 1898 another attack laid him by for twelve weeks, and again in January, 1901, he was confined to bed for fourteen days. The pains during these attacks on the left arm were very severe, but receded gradually as the arm continued to improve. Six weeks ago the patient was reattacked in a similar manner, for which he was brought to hospital, and where he has remained with the same repetition of improvement. The arm at the present time seems perfectly healthy, and has increased 4 centimètres below the elbow within the last four weeks. The sensibility has returned to its normal condition, and volition, as may be seen by the patient's movements, which are perfect. When he was received the pain in the limb was intense, but was soon relieved by ordinary sedatives. The diagnosis of the case is somewhat complicated, being remittent in its history, and appears to be one of atrophic paralysis of the muscles of the left arm arising from trophic disturbance and defective sensibility. The recurring stasis and progression of the disease, associated with occasional extension, gives an obscure colour to the clinical history of simple progressive muscular atrophy. It would appear that the subjective and objective signs of disturbed sensibility are absent, owing to their frequent remission, neither is there any pain in the spinal column that can be located. In the case of any pathological growth in the cervical region this retrogressive course could hardly be entertained in a case of intra-medullary tumour or meningeal changes. The diagnosis may thus be reduced to a simple inflammatory process of the ganglionic cells in the grey matter in the anterior horns of the cord or in the nerve itself, and thus reduced to a case of poliomyelitis or probably polyneuritis.

Nothnagel observed that the skin of the left atrophic arm was much thicker than the skin over the right. This thickening of the skin he had often observed over atrophic muscles and bones, and which had often been referred to at the discussions of these meetings as a symptom closely associated with poliomyelitis acuta atrophica in children. The symptoms in these cases he admitted.

Winter Health Resorts.

INNSBRUCK.

[FROM OUR OWN CORRESPONDENT.]

"Nowhere else in the world can be found a town of equal importance placed amidst a landscape of such lofty grandeur and ideal beauty."

Innsbruck is chiefly known to travellers as a convenient resting-place, situated as it is at the junction of several important trans-Continental railroad lines. As a Health Resort, its many advantages are as yet very insufficiently known and recognised. Yet very few Continental places can offer anything even approaching in number and importance these hygienic advantages. Its situation is excellent. It lies in the long wide valley of the River Inn, over 1,900 feet above ocean level, thoroughly safeguarded by a high range of the Bavarian Alps from northerly winds, and fully open to the warm southern sun and south winds of Italy.

Innsbruck has an equable, cold, dry climate, and throughout the bleakest wintry seasons the unique combination of an Italian sunshine with a luminous, dry, mountain air makes its atmosphere a delicious yet positive tonic for the elderly, the delicate, and the convalescent. A cold north wind is unknown here, even in winter. For weak and overgrown children, for those annoyed with sleeplessness and poor digestion, and especially for those suffering from stomachic troubles and similar sequelæ of influenza, a sojourn at Innsbruck will be most beneficial.

As a preventive remedy for any, young or old, predisposed to asthmatic and pulmonary diseases, a winter at Innsbruck is very desirable, and in various ways preferable to what is really a "banishment" to some of the higher and isolated Alpine resorts. The merits claimed for such high stations are likewise found equally at Innsbruck, viz.:—Deepness and purity of atmosphere; absence of objectionable winter winds; freedom from fogs and from persistent cloudy weather; brilliant sunlight; intensity of solar radiation. And together with these merits, at Innsbruck are also found what are not combined at high altitudes elsewhere, namely, all the amenities and attractions of active and flourishing city life—university, colleges and schools, great churches, cathedral and military music, libraries, museum, fine streets and shops, elegant villas, all winter sports, excellent hotels (kept both on English and Continental methods of cooking and of living) at prices very moderate in the leading houses, and very economical yet good in the smaller establishments, so that all preferences and purses can be suited.

In an able article on the preventive treatment of phthisis, Professor Jaccoud, of the Paris Faculty of Medicine, sums up the results of high-altitude experience in the following formula:—"During summer the highest altitudes; during autumn and winter, lower altitudes having the winter characteristics of mountain climates." Writing specially about the treatment of young people, not invalids, but predisposed to pulmonary disease, he recommends that they and their families should not be banished for the long months of autumn and winter to rural or semi rural spots. On the contrary, he recommends as the better method to send them to places where all the merits of a winter home can be found combined with the advantages of a city life. Enumerating at length the points in favour of Innsbruck—its mountainous surroundings, its historic reminiscences, its equable temperature, dry and health-giving atmosphere, picturesque position, numerous promenades and excursions, artistic and intellectual resources, social and material conveniences—"equal to those of the greatest capitals of Europe"—the Professor closes by pronouncing "this city of the mountains, Innsbruck, from the medical point of view, a winter residence admirably privileged."

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

Two Cases of Strangulated Hernia.—Mr. Battle operated on a case of strangulated inguinal hernia in a young man, æt. 24. The patient said that he had had a rupture on the right side when he was a boy, but that it had become cured; more recently there had been some swelling in the right groin, but this had not troubled him until the night before admission, when he had suffered severe pain, and noticed that the swelling was larger and he could not get it back again. He had vomited and been unable to sleep on account of the pain, and there had been no action of the bowels. The case was one of strangulated congenital hernia, and the tumour, which was the size of two fists, was situated entirely above the scrotum. The right testicle was not descended, and could be felt in the wall of the sac. The percussion note was dull over the sac, which last was very tender to the touch. An oblique incision was made over this, and the sac opened; a little brown-stained fluid came away, whilst the rest of the sac was occupied by a loop of small intestine about eight inches long, which was absolutely black. It, however, retained its polish and its elasticity. The constriction, which was at the internal ring, was relieved, and after the bowel had been examined at the place where it had been constricted, it was washed with warm sterilised saline solution and returned into the abdomen. The atrophied testicle was removed, and the sac cut away after ligature of its neck. The structures were then sutured after Bassini's method, and the wound closed without drainage.

The second case was that of a man, æt. 45, who was admitted with a strangulated femoral hernia on the left side. The history was that of a hernia on the left side for some years and of strangulation for two days. There was a femoral hernia about the size of a walnut in the left groin which was irreducible, resistant, and tender. There was also a swelling in the left inguinal region in the situation of the external ring which could be reduced on pressure and gave an impulse on coughing. The patient evidently had two hernias, of which the femoral was strangulated. At the operation a vertical incision was made extending over the femoral and inguinal swellings. It was found that the femoral sac contained a small loop of congested intestine, which was easily reduced after division of Gimbernat's ligament, whilst the inguinal swelling was a direct hernia and contained no bowel at the time of operation. The external oblique was slit up along the line of the canal, and after ligature of the neck of each sac that of the femoral sac was drawn above Poupart's ligament, and the structures sutured as follows:—The opening in the conjoint tendon was closed by the silk suture, which carried conjoint tendon behind the cord and attached it to the fascia over the pectineus below the neck of the femoral sac; other stitches were inserted to draw conjoint tendon to Poupart's ligament; the outer wall of the femoral canal was sutured with interrupted silk sutures, and Poupart's ligament was approximated to the pectineal fascia by means of two more. The wound was then closed without drainage. Mr. Battle said the first case was an example of the rapidity with which serious changes take place in the intestine when strangulated in a congenital hernia; the duration of strangulation was less than twenty-four hours, and yet the gut was absolutely black, and a few hours longer without relief must have rendered it gangrenous. In the second case a combination of a direct inguinal hernia and a strangulated femoral was an unusual one, and the method adopted of producing a radical cure after the operation for strangulation appeared, was he thought, the best possible under the circumstances. He had only met with one example of a similar condition that required operation before.

Both cases made a satisfactory recovery.

REGISTERED FOR TRANSMISSION ABROAD.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 31, 1902.

ANNO DOMINI, 1902.

THE past year has not, perhaps, been distinguished by any of the great epoch-making advances which have from time to time characterised the history of medicine. Much has been done to advance and improve the position of medicine, but this has been done rather by criticism and the development of the knowledge we already possessed than by any startling addition to it. The death on September 5th of Rudolf Virchow, who may be said to have been the very founder of modern pathology, and who during the last fifty-five years occupied a foremost place among the leaders of science, will ever make the year 1902 a memorable one. Virchow's great work was no doubt accomplished; by the training of his pupils he had made provision for its continuance, and by his example and methods he had shown how that advance might be maintained; but the passing of the great master-mind which had fashioned this science and had so long directed its progress must of necessity leave a blank and make us pause, if only for a moment, to consider the heritage he has left us.

The epidemic of small-pox which invaded London during the second half of last year reached very considerable dimensions before it was got under control, and even yet the disease cannot be said to be completely stamped out. That an epidemic of small-pox in London should, in the twentieth century, cause over a thousand deaths does not speak well for the intelligence of the British public, or for the success of the teaching of preventive medicine. The facts, however, brought out by this epidemic are of the utmost value, and should form a conclusive answer to the anti-vaccinator, were that individual open to argument or capable of the reception of truth. We fear that he possesses neither of these qualities, and his pernicious influence still continues to help in the propagation of disease. The figures relating to the epidemic in London published in the Registrar-General's return for the week ending April 12th, 1902, afford conclusive proof, as far as such proof is possible, of the immunity conferred by efficient vaccination and re-vaccination.

They show that among the vaccinated attacked with small-pox during the present epidemic 99·3 per cent. of the deaths were among persons over ten years of age; while among the unvaccinated the corresponding percentage of deaths over ten years of age was only 42·7. It is a matter for congratulation that the disease, though introduced into Dublin, was unable to obtain a footing there, and we trust that it will be a long time before Ireland has to add the introduction of the anti-vaccinator to the list of grievances which she has against the sister country.

The formation of the Imperial Vaccination League, which held its first meeting on December 12th, will do much to further the vaccination and re-vaccination of the community.

The experience of the South African War has had the result of directing the attention of the profession very strongly to the question of the prevention of enteric fever. There can be no question that from the medical aspect enteric fever occupies the foremost place in that campaign. Complete statistics are not yet forthcoming in regard to this outbreak, nor is the information at our disposal as yet sufficient to enable us to make a final pronouncement as to the prophylactic value of Professor Wright's anti-typhoid inoculation. From those figures which have already been published it would appear that the vaccine is of very considerable value, but that the results are not uniform, and that the conditions which determine this want of uniformity are not yet fully understood. If, for instance, we look at the official figures for the garrison at Ladysmith, we find that in enteric there were among the inoculated 1,705 cases, or 2 per cent.; among the uninoculated there were 10,529 cases, or 14 per cent. It would appear that even some who contract the disease and recover from it, do so with an immunity which is below that of the ordinary individual. In other words, the attack appears to have lessened the normal resistant power of the individual, so, too, after inoculation the normal resistant power may be lessened. Whether this result can be avoided or not is at present undecided, and much experimentation will probably be necessary before it can be settled. Considerable advance has been made in our knowledge of the extra-corporeal life of the typhoid bacillus, and in this connection the paper contributed to the Pathological Section of the British Medical Association by Majors Firth and Horrocks is one of great importance, as is also that of Dr. Sidney Martin in the report of the Local Government Board for England for the year 1901-02.

As a result of the experiments there set forth it would appear that the bacillus typhosus has a much more extended existence outside the human body than was formerly supposed. For instance, these observers found that from a piece of karki drill fouled by liquid enteric fæces and then allowed to dry, the micro-organism is recoverable on the seventeenth day. Some few years ago bacteriologists appeared quite satisfied with regard to the etiology and mode of dissemination of enteric fever, but recent investigation has thrown doubts on the accuracy, or rather on the completeness, of our information on these subjects. At present the doctrine that there are several strains of the enteric bacillus, all pathogenic, all producing more or less completely the facies of typhoid fever, but yet not wholly identical and not capable of producing complete mutual immunity against infection by the other. The differentiation of the bacillus typhosus from the bacilli of the enteritidis group cannot yet be said to be satisfactory. Blumenthal in the *Deut. Med. Woch.*, August 28th, recorded a case in which the patient died after an attack of apparently typical enteric fever, in which a positive Widal reaction had been obtained, and although death was supposed to have occurred on the twentieth day of the disease and the bacillus typhosus was recovered from the spleen and lymphatic glands, no typhoid ulcer was found in the intestines. In view of these facts there will, it appears, have to be a revision of our conceptions of this disease in the near future.

The war against consumption, which was started with so much brilliancy last year in London, has settled down into a steady blockade, and already there is evidence of the good results which may be expected from it in the future. Sanatoria are springing up throughout the country, and the lay public appear to be awakening to their duty in the matter. There is, perhaps, no disease in regard to which so much good may be expected from the rigid application of the rules of preventive medicine as tuberculosis. At the International Conference on Tuberculosis, held in Berlin last October, Professor Koch still maintained his opinion, in spite of much opposition, that human and bovine tuberculosis are distinct diseases, and is reported to have enunciated the further opinion that boiling does not sterilise milk, but merely renders it unwholesome. We trust that these opinions will receive more proof than the mere weight of Professor Koch's opinion before they are generally adopted.

The illness of the King and the operation which was so successfully performed on him naturally directed much surgical attention to the subject of appendicitis, and this was further enhanced by the attack from which the wife of the Viceroy of Ireland is now happily recovering. Little, however, that is new has been added to our knowledge of the disease or its treatment. The indications for treatment have been, perhaps, more clearly formulated, but the results still leave much to be desired. One of the most striking features of the surgery of the year is the growth of that tendency, which has been so evident lately, for the surgeon to invade that domain which was formerly looked on as purely medical. Many operations have been done with varying results to relieve the symptom of ascites in cirrhosis of the liver. The results of operations for the cure of gastric ulcer have been most satisfactory, not only in those cases in which perforation had taken place, but also when undertaken on account of hæmorrhage and intractable dyspepsia. Operations have also been undertaken for the cure of chronic Bright's disease, but apparently without much success. G. A. Schmitt, of New York, in an analysis of the cases already recorded, ends his article with the following significant remark:—"Before long the surgical treatment of chronic Bright's disease will probably become fashionable, until mature experience and sober judgment have exposed the fallacy of the proceeding."

On December 9th, 1852, Joseph Lister was admitted a Fellow of the Royal College of Surgeons, London, and during this year the medical profession celebrated the jubilee of that entrance. It is difficult for the young surgeon of the present day to appreciate what he owes to the labours of Lord Lister—labours which have enabled surgery to reach its present position. Some fifty years ago surgery was said by an eminent authority to have reached its zenith, and so perhaps it had, were it not for the introduction of antiseptics and anæsthetics. He would be a courageous man who would now attempt to put a limit to its future development. With asepsis replacing antiseptics, and with our increased knowledge of the functions of the internal organs of the body and improvements in technique, it seems impossible to define its limit.

On July 31st Royal assent was given to the Midwives Bill, which now, after many years of discussion, passes into the Statute Book as the Midwives Act, 1902. It remains to be seen how this much-abused Act will justify the hopes of its supporters.

It would appear that the dispute between the two Royal Colleges in England and the General Medical Council is approaching a final stage. At the request of the Council, the colleges have furnished particulars as to the work in institutions the competence of which had been questioned. These particulars are now to hand, and go far to justify the position which the Council adopted. Of the sixty-two schools recognised by the Colleges and refused recognition by the Council it would appear that no fewer than ten give only one hour a day to the study of science subjects, which even the colleges, we imagine, will consider insufficient If they once admit this, they also admit that they have been fighting in defence of a position which is untenable, and the proper course for them now to adopt is to frankly admit their error.

The question of the conflict of medical evidence in courts of law has again been brought prominently before the notice of the profession in Ireland by the address delivered at the opening meeting of the surgical section of the Royal Academy of Medicine by the President of the Royal College of Surgeons. That something should be done, and that in the near future, if the profession is to maintain its honourable position is evident, but what that something is, is difficult to decide. If, as appears to be the case, the Bench and Bar refuse to join with the medical profession in an attempt to remedy the evil, which they all admit exists, a solution appears impossible.

PLAGUE SERUM AND TETANUS.

From time to time medical men are forcibly reminded of the responsibility attached to the exercise of their profession. It is only by fully informed unceasing vigilance that they are enabled to secure a reasonable amount of safety for a large proportion of the patients submitted to their care. In the exercise of aseptic or antiseptic surgery, for instance, the omission of a single minute precaution may be fraught with the gravest consequences for all concerned. Indeed, it may be said that to acquire a thorough knowledge of Listerian methods in itself constitutes a liberal education. How much the present generation of medical men owe to the grasp both of principles and of details thereby entailed it is impossible as yet to estimate with any degree of accuracy. With the increasing field of scientific knowledge, especially as regards bacteriology, it has been possible to reduce aseptic surgery more and more to the position of an exact science. A similar observation applies, although, unhappily, with nothing like the same extent, to the valuable protective measure of vaccination against small-pox. By degrees scientific medicine has learned how to reduce very materially the chances of contamination by stray micro-organisms by carefully guarding the vaccine, the skin of the patient, and the instruments and hands of the operator. There can be little doubt that sooner or later means will be found to render the process of vaccination absolutely safe from contamination with organisms other than those which confer its specific preventive powers upon the vaccine matter. As a rule the newly-introduced protective serums are fortunately free from dangers of contamination, and are consequently safe if administered with proper precautions by skilled hands. Not very long ago, however, the occurrence of tetanus in a patient who had been treated hypodermically with a particular serum as a cure for aneurysm warned the profession of a deadly danger attached to the serum method. We regret to say that a similar unfortunate result has happened in India on a much larger scale. Shortly before Parliament rose Lord George Hamilton, in answer to a question in the Commons, said that unfortunately some twenty deaths had occurred in India from the use of "putrid" plague serum. Later reports confirm the news, and supply the further information that the deaths were the result of lockjaw. A few days after Lord George's answer in the House a medical correspondent of the *Daily News* wrote, saying that from private information he inferred the deaths occurred from the use of serum contaminated with tetanus organisms. It seems hardly probable that Lord George Hamilton was not in possession of that specific knowledge, in which case it is hard to imagine what good end could be secured by suppressing the naked facts of this most unfortunate affair. With regard to the matter it is impossible to forget that the presence of tetanic organisms in a sterilised serum like that used against plague is entirely and absolutely preventible, both as regards the laboratory where the drug is prepared and the operator by whom it is administered. The upshot of the whole affair will undoubtedly be a sweeping reform of laboratory methods and of anti-plague serum administration. It is only by the greatest caution and vigilance that the confidence of the natives can be secured and maintained in what is the most valuable means yet discovered by the wit of man to combat a terrible zymotic malady.

HOSPITALS AND POST-MORTEM EXAMINATIONS.

The anomalous position in which hospital pathologists have been placed by the interposition of Dr. Freyberger is entering upon an acute stage. Mr. Troutbeck, the Coroner for Westminster, who has formally taken up the championship of the new departure, declares that the reform is one which has long been needed, and he denied the right of any man, however distinguished to claim to give evidence before the jury. This remark is, of course, aimed at hospital pathologists, but it is singularly inappropriate, since the appointment for which the coroner was pleading creates the very monopoly which he deprecates. A hospital pathologist is a highly qualified man with special and usually extensive experience in carrying out post-mortem examinations, and he performs his duty before a public composed of students and members of the medical staff with but one object, viz., the elucidation of the cause of death, without fear, favour or affection. But Mr. Troutbeck proceeded to give a *jugement motivé*. On the strength of a pronouncement of Dr. Freyberger's in respect of the case of a youth who had died under chloroform at St. Thomas's Hospital, the jury were persuaded to express the opinion that a better system of examining patients about to undergo an operation was necessary. As a matter of fact, the routine examination of patients seldom reveals anything which can indicate whether such patient is likely to take the anæsthetic well or not, and after reperusing Dr. Freyberger's evidence at the inquest referred to we are constrained to assert that in so far as they bear on the inadequacy of the previous examination they do not repose on any scientific basis. We are quite prepared to admit that economy is not of itself a detail worthy of consideration in view of the weighty issues at stake, and it is to be regretted that the question of cost has even been mentioned in this connection. Another argument made use of by Mr. Troutbeck was that the post-mortem examination of the person whose death was under investigation had not been thoroughly performed, in that the intestines had not been examined. This, it must be conceded, was a serious omission, especially as the examination had failed to establish the cause of death. Dr. Freyberger complained, moreover, that the tonsils, the thyroid, the thymus, and the bladder had not been examined, to which he might have added that the pineal body, the testicles, and the floor of the fourth ventricle had also escaped observation. Far from experiencing any difficulty in explaining the cause of death, he saw at once that "it was due to heart failure accelerated by acute congestion of the lungs (of which no mention has been made) and overloading of the stomach in a lymphatic subject." Nothing is easier than to "ascribe" a cause of death in the absence of precise anatomical data, but it is the merest conjecture, except, perhaps, in so far as the failure of the heart is concerned, since this is pretty constant at death. We regret that the question of the appointment of an official pathologist should have come to the front under such unpleasant circumstances. It is an innovation which we have urged for years, convinced as we are that medico-legal examinations involve issues far too grave to be confided to inadequately skilled hands. If feeling has been aroused the fault lies with the almost surreptitious way in which the appointment was made and the want of tact shown by the Coroner for Westminster in pitting the neo-pathologist against hospital pathologists of unexceptionable attainments.

THE order of the London County Council in respect of the notification of chicken-pox expires on January 6th.

Notes on Current Topics.

Hereditary Liability to Tuberculosis.

ON the heels of Koch's discovery of the tubercle bacillus there soon came the fact that tuberculosis is not an hereditary disease. But old beliefs die hard, and the assumption was made that although tubercle bacilli were not transmitted from parent to child before birth, yet there was a particular constitution running in families which had a direct liability to tuberculous infection. That is to say, the suitable soil for the growth of the disease, though not the disease itself, was supposed to be hereditary, or, as the old dictum expressed it, "we are born scrofulous—we become tuberculous." But now it seems as if even this poor substitute for a venerable dogma of the medical creed must go, for a careful investigation shows that the difference of the incidence of the disease in the offspring of tuberculous and non-tuberculous parents is very small. If this is so, keeping in view the much greater opportunity for infection afforded to the former class, it would appear that instead of having transmitted to them a tendency toward the disease, the children of tuberculous parents have in fact received a certain congenital immunity. This is the theory lately put forward by Dr. Arthur Latham, the winner of the King's Prize, and supported by some strong arguments. We know, for example, that animals can be rendered immune against some diseases, such as anthrax, and that this immunity is transmitted to the next generation. Again, when certain diseases, such as measles or syphilis, have been epidemic in a country for a long time, they get milder in type, as if the entire community had become more or less immunised, while on the other hand they are exceedingly virulent if introduced to a country where they have been hitherto unknown. Further, the blood in advanced cases of tuberculous disease gains the power of agglutinating Koch's bacilli, a property undoubtedly in some sort protective, whatever be its exact nature. It is possible that this effort may be in some cases successful, and that it may be transmitted. The subject is not only of great interest theoretically, but of much practical importance, and anything that tends to throw light on it should not be missed.

The Japanese as Sanitarians.

IT would be difficult to find a more marked example of what good sanitarians may accomplish than the present condition of the Island of Taiwan that, from being a plague-spot, has become, under Japanese rule, a sanatorium. By the treaty of Shimonoseki, in 1895, the island, which is the eastern escarpment of what was once the great Malayo-Chinese continent, became Japanese territory, and its three millions of inhabitants became subject to Japan. They were most unpromising people to deal with. On the east coast they were wreckers, while inland they cultivated rice and prepared camphor for the Chinese and European markets. Of the two millions and a half of Chinese almost all were opium eaters and smokers; the one hundred thousand Malays were known on the island as "savages." Great unclaimed marshes stretched from Mount Morrison to the lagoons at the Western shore. Malaria and dengue were endemic, dysentery was common, and in the cities Jaihoka, Jamusi and others continued fevers were ever present. Under Japanese rule the use of opium was prohibited, except as a medicinal agent prescribed by a physician. The city slums were pulled down, the narrow streets widened, every house was after a given date to be unoccupied until its sanitary arrangements were approved of by the sanitary authorities. A very excellent drainage system was made compulsory in every city, artesian wells were sunk for drinking water, and the roadways kept in good repair. In the seven years of Japanese rule mosquitos have become almost unknown, dysentery of the acute form has disappeared from the latest list of diseases; continued fever is the exception in the cities of the island. But this is not all; railways are being constructed so as to form a network over the country; telegraphic communication connects the island with China on the one hand and Honshin on the other; and, lastly free schools are established all over the country, and compulsory education is strictly enforced. In the schools every child is taught the rudiments of sanitary science. The whole rising population are indoctrinated with the belief that disease is largely due to want of cleanliness in the homes and persons of those attacked. The nearest approach to this thoroughness in enforcing sanitary laws occurred under the able administration of General Woods, U.S.A., when he was placed in charge of Cuba after the Spanish War of 1894. In both cases disease was driven out by application of sanitary laws.

Locomotor Ataxy.

THE treatment of locomotor ataxy by the internal administration of medicines is, unfortunately, seldom followed by good results. The failure has been confessed both at the Surgical Congress of Moscow and at the Twelfth Berlin Congress. Hydrotherapy and massage have not realised all that was hoped for from them in this disease; but Anders Wide, of Stockholm, asserts that the ordinary methods of massage are useless in the treatment, and he lays down a special code of directions, such as are followed in the medical gymnasium of Sweden, under his care. Placing the patient on a stone or strong wooden couch the masseur commences by circumducting, flexing, and extending the limbs. The patient is then placed astride the couch, as if on horseback, and circumduction of the trunk is practised; this is followed by placing the patient on his face, in an extended position, and pressing and percussing his spinal nerves. It is unnecessary to enumerate the different processes, suffice it to say that Wide looks on the rigidity of the muscles and the pains that are so characteristic of the disease as due to a toxin, and that the poison is eliminated by a systematic, properly-conducted massage of the whole body. Zablindowski reports most favourably of the method, and quotes cases in which the power of locomotion without any aid was restored. Rigidity disappeared and sensation returned. Muscle tissue recovered its tonicity, and the girdle and lightning pains ceased. Yet even better results are obtained when, as M. Konindjy points out, massage is associated with gymnastic exercises calculated to educate muscular co-ordination, to group muscles to act harmoniously, as is done when by accident the right hand is lost and the sufferer educates his left hand to perform the duties formerly done by its fellow. At home, Aethus and Granville more than twenty years ago recommended massage as a treatment for tabes dorsalis, but the practice was in time discontinued. We think that the combination of the methods of massage and educational gymnastic exercises offers such a hopeful prospect for the victims of the disease that it should be more generally adopted. It is a treatment based on sound scientific principles.

The New Inebriates Act.

THE provisions of the Inebriates Act, which come into action with the commencement of the New Year, can hardly fail to have a far-reaching effect upon the liquor trade. They affect profoundly the relations of the police and of the publican to the drunkard. A police-constable will henceforth have the right to search any part of a publican's premises if he has reason to suspect that they harbour a drunken person. The police have also largely increased powers with regard to the control of inebriates. One reform is likely to be of considerable service, namely, that which increases the responsibility of the publican for drunkenness upon his premises. At present the holder of a license cannot be convicted unless it be proved that any person found drunk reached that condition through carelessness or connivance on the part of himself or his servants. The recent Act, however, is far more stringent, and provides that "where a licensed person is charged with permitting drunkenness on his premises, and it is proved that any person was drunk on his premises, it shall be with the licensed person to prove that he and the persons employed by him took all reasonable steps for preventing drunkenness upon his premises." The new Act certainly registers the greatest step towards the legislative control of the liquor trade that has been taken for many years. It is to be hoped that drastic legislation will be followed by energetic administration.

The Administration of Anæsthetics.

CATASTROPHES resulting from the employment of anæsthetics are likely to receive closer scrutiny in the near future than they have received in the past, from the point of view of the responsibility of the administrator, so that the subject merits our attention. Deaths occurring under chloroform or other anæsthetic may be distributed in several groups. First, there are the cases in which the anæsthetic is blamed in the absence of other discoverable cause of death, and these are of necessity very frequent. Secondly, there are cases in which the action of the anæsthetic on organs already diseased unquestionably precipitates the fatal termination. In chronic disease of the lungs or kidneys, in diabetes, in the obese, and in operations on the mouth, larynx and brain, the employment of chloroform or ether may turn the scale against the patient, and when existence of disease is known beforehand the administration of oxygen in combination with either chloroform or ether may avert otherwise inevitable death. There is a third class, the importance whereof it is naturally difficult to ascertain, in which death is due to improper administration or to overdose of the anæsthetic. These cases belong to the strictly preventible deaths, and ought never to occur; but so long as anæsthetics are given by men who have received no special training, and who have had little or no practical experience, they will continue to happen. Nor can they be prevented by any hard and fast regulation, seeing that, in country practice at all events, it is often necessary to administer an anæsthetic under circumstances which preclude the employment of a professional anæsthetist.

Typhoid and Appendicitis.

Although M Dieulafoy has laid down the dogma that no one should ever die of appendicitis, and his opinion on this head has been subscribed to by many other experienced clinical observers, the occasional exception, which some may say but proves the rule, is sometimes presented in a very emphatic form. In a recent clinical lecture, M. Rendu, of the Necker Hospital, brought before his audience an interesting example of complex diagnosis in this connection. A vigorous-looking woman of twenty-nine was admitted, who had been suffering from severe headache for fifteen days. There was general malaise, with anorexia, constipation, and a general sense of weight and discomfort all over the abdomen, but not definitely localised. For some days there had been a well-marked evening rise of temperature. Deep-seated pressure in the right groin caused pain, and an almond-sized swelling was found in the broad ligament. The cervix uteri was also enlarged. A diagnosis of salpingitis was accordingly made. The patient improved under treatment, and at the end of twelve days was considered well enough to leave the hospital. She then suddenly developed a violent rigor, with severe headache and rapid elevation of temperature (to 39·6° C.), but there was no vomiting, nor abdominal pain, nor tympanites. On the following day there was marked pain at McBurney's point, but very little muscular tension. Diagnosis of appendicitis was then made. As the patient grew worse, operation was decided on—four days later. The appendix was very much congested, and contained a blood-clot, but there was no peritonitis and no adhesions. Six days later she died. On the day before death, Widal's reaction gave a positive result; but till the post-mortem examination the diagnosis of typhoid was not definitely concluded. Then the intestinal lesions were found to be perfectly characteristic. Still, the union at the seat of operation had been perfected by first intention.

Local Journalism and Local Practitioners.

The undesirability is generally recognised of anything that savours of the advertisement of medical men in lay newspapers. In spite of that unwritten law, however, the growth of the "puff oblique" goes on apace, if we may judge by the unceasing stream of complaints that flows through the correspondence columns of the medical journals. Our attention has been in that way drawn to a recent copy of the *Bournemouth Graphic*, an illustrated newspaper which displays the energy of exuberant youth in its editorial functions. One of its features has been the publication of the photographs, together with descriptive interview or notice, of all Bournemouth medical practitioners who are the fortunate owners of motor-cars. One medical man is reported to have made a sage remark to the effect that motor-cars, like human beings, were apt to get disorganised now and then, and that two of his own vehicles were at that moment under the motor doctor's hands. The artistic possibilities of this form of notice are apparently as varied as they are objectionable. A vigorous protest on the part of the local medical society would probably have a beneficial effect in protecting medical men from such gratuitous annoyance.

Appendicular Actinomycosis.

In August last, M. Poncet recorded a case of actinomycosis of the vermiform appendix, and another case of this very rare condition was published by Dr. Leon Thevenot (of the University of Lyons) on November 18th. The patient had been for some time employed as a stable-boy in an hotel, and had previously been a farm labourer. He had been the subject of hydrarthrosis of the right knee-joint at the age of fifteen, but had made a rapid and complete recovery under treatment. He had lost three or four molar teeth during the past three years, from caries. He had long been in the habit of chewing blades of grass, grains of wheat, &c., when not quite ripe. His symptoms dated from May 1st, when he began to suffer from acute pain in the right iliac fossa. There were recurring rigors, frequent nausea, and progressive malaise and debility. The temperature was elevated (38°-39° C.). He went into hospital at Belleville, where his symptoms improved under treatment by rest, careful diet, and inguinal compresses moistened with laudanum. He was then sent on to the Lyons Hospital (L'Hôtel Dieu). There was then no inguinal pain; but he suffered from lassitude and persistent anorexia—with slight constipation. There was little emaciation. There was no pain at McBurney's point. A small tumour was found above Poupart's ligament on the right side. It was of about three or four fingers' breadth—in vertical direction, and was very hard. The diagnosis of appendicitis—probably of the nature of actinomycosis—was then made; and the operation of removal of the affected organ was successfully carried out. A good recovery followed. Although the condition is relatively so rare, Hinglais was able to collect 120 cases in the thesis which he published on this subject in 1897. Since then nearly thirty others have been recorded.

Intra-spinal Cocainisation.

THE intra-spinal use of cocaine for the production of analgesia has been known since 1884, but up to quite recently it has only been used for operations on the lower limbs and lower parts of the body. While local analgesia of this kind possesses many advantages over general anæsthesia, our experience of cocaine has not yet been sufficient to establish its uniform safety; and some of the after-effects have occasionally been very troublesome. Mr. Morton, of San Francisco, however, has recently published his experience of 643 cases (*Journal of the American Medical Association*, November 8th) without a single failure. He has also enlarged the sphere of its use by showing that the analgesia extends not only to the legs, but also to the arms and upper parts of the body. For instance, he has amputated the arm and fingers five times, has trephined five times, and has removed tumours of the face seven times, by the help of spinal cocainisation. His method is in all cases to dissolve the cocain hydrochlorate (0·3 to 0·5 of a grain) directly in the cerebro-spinal fluid, by allowing the latter to run into the syringe. He believes that by this means better diffusion is obtained, and there is less chance of failure. The injection is made in the third lumbar interspace. Analgesia of the lower part of the body is complete in from three to five minutes, and in the upper from fifteen to twenty-five; it lasts from one to five hours. None of the cerebro-spinal fluid should be allowed to escape.

Coroners' Courts and Hospital Consultants.

OUR attention has been drawn by a correspondent —whose letter is printed in another column—to the extraordinary attitude of one of the honorary surgeons of a London hospital. The gentleman in question, in giving evidence before the Coroner's Court as to a person who died under an anæsthetic, protested in emphatic terms against his being called as a witness. His statement that his time was valuable and that he was losing a great deal of money by attendance at court was probably made in the heat of the moment and need not be seriously considered. His general attitude, however, demands more consideration. It cannot be too clearly understood that any member of the medical profession appointed to an honorary position on the staff of a public charity must accept its accompanying responsibilities. In more than one case mentioned by our correspondent, members of the honorary staff have ignored the coroner's summons and sent in their stead a resident medical officer. In case of a summons it would be well for the honorary surgeon or physician to communicate with the coroner, who would then be enabled to judge whether it would be desirable to dispense with the evidence of the former. It is hardly needful to point out that anyone wilfully disregarding the summons of a court of law is placing himself in a false position which might entail consequences of an extremely unpleasant nature. In the particular instance of deaths under anæsthesia it is desirable that the highest skilled testimony should be available, and, for that matter, in many other cases as well. On the whole it is not improbable that a mere hint will suffice to prevent future complications of the kind suggested by our correspondent.

Electrocution in a Public Bath.

LAST week the dangers of electric lighting were illustrated by a most deplorable accident in a London public bath. The attendants at the institution in question were attracted by the cries of one of the bathers, and on going to the spot found him in an agony of pain and suffering from shock, which shortly afterwards proved fatal. Another man was found dead in an adjoining bath. The cause of death in both instances appears to have been electrical shock. Pending an official inquiry into the occurrence, the probable explanation is that the baths became connected in some way with the wires conveying the current for lighting purposes. It is difficult to imagine any other way in which a powerful electrical discharge could have reached the bath. The incident should attract the attention of all responsible for baths, both public and private, in every part of the United Kingdom. If the use of electrical lamps is to involve the risk of electrocution, then the public will undoubtedly prefer the substitution of less dangerous illuminants.

The Results of Milk Inspection in America

The Medical Society of the County of Albany have lately discharged a most important public work in appointing a committee to examine bacteriologically samples of milk taken from the numerous milk dealers of Albany County. The results thus obtained show the extreme need which exists for regular supervision in the case of the milk supply of a country. Sixty-five specimens in all were examined, and of these nine contained pus, while in at least one the sediment showed streptococci and staphylococci in abundance. Some of the specimens contained 3,000,000 bacteria per c.c., while one in particular contained nearly 10,000,000 bacteria per c.c. In some cases, on the other hand, the count of bacteria yielded results which suggested the use of preservatives. As Supporting clinical proof of the impurity of the milk supply comes the fact that, although the past summer was not so hot as usual, the number of deaths reported as being due to diarrhœa was greater. It appears from the report of the committee that dealers attempt to sell what presumably is by courtesy termed milk at six cents per quart, while, according to the opinion of the committee, it is impossible to sell the pure article at such a price. The question of impurity in the milk supply, even though in this case the facts relate to America, is of considerable practical interest to medical men in the United Kingdom. There can be no doubt that an enormous amount of loss of infant life, and permanent bad after effects in the case of those who survive, is caused by the present system of milk supply. Some time or other local authorities will have to tackle the question of the provision of a proper supply, and with a view to its solution, every item regarding the milk supply of other countries will be of value.

"Favourable Results."

A CYNICAL critic observes that we hear far too much of "favourable results," both in medicine and surgery. Literature is full of the records of cases which have terminated in favourable results, and their prevalence is such as to give rise to an uneasy suspicion that we are not reading the annals of medicine but merely the annals of somebody's. successes. The object of medical literature is, or should be, the generalisation of useful knowledge and it would be absurd to pretend that "favourable results" alone convey all knowledge worth having. On the contrary, the wise man, it has often been observed, learns more from his failures than from his successes. Medical pictures should not be monochromes, for these fail to give prominence to possibly important details. To say that medical men, being men, are more prone to publish their successful, rather than their unsuccessful, cases is an explanation and not a justification of the practice. The experience of others may be useful to the practitioner, provided always that it be fairly and honestly conveyed, and o be honest it must be complete.

Plague in California.

VERY great indignation is felt throughout the United States of America at the determined manner in which the presence of plague in San Francisco has been denied by the State and City Health authorities, and their equally determined policy of inertia. Plague is known to have occurred in the city as long ago as March 1900, from which time to the present there is no reason to believe it has ever disappeared. In spite of the absolute suppressions of facts by the local authorities, as many as thirty cases are known to have occurred in the three months July to October of this year, and the real number is probably much greater. Governor Gage, the Governor of the State, has been foremost in the policy of denial, and has actually succeeded in obtaining the removal of Surgeons Kinyoun and White of the United States Marine Hospital Service who had shown a proper zeal in their endeavour to cope with the disease, while two bacteriologists were dismissed by the State Board of Health for making a positive diagnosis of plague in cases submitted to them for examination. A bill was introduced to the legislature by the Secretary of the State Board of Health, making it a felony to print or publish or to make in writing a report of plague or cholera before a public announcement had been made by the State Board. It is noteworthy that as long ago as 1900 Surgeon Kinyoun was offered by six Chinese companies a bribe of 40,000 dollars to suppress the facts: and there is reasonable ground for supposing that others have been less scrupulous than he. It is hardly to be wondered at that the delegates of the State and provincial Boards of Health of North America recently assembled at New Haven, in view of the history of the epidemic, as far as it was possible to discover it, should have decided on requesting the Surgeon-General of the United States Marine Hospital Service to summon a national conference to put an end to the scandal in California.

Chauvinism in Medicine.

IN our reviews of books both English and foreign our readers must frequently have observed the stress we have had to lay on the ignorance commonly shown by authors of previous work done in their particular subject in any country but their own. This ignorance in many cases is due to simple indolence, but is sometimes, it is to be feared, a deliberate act connected in some way with perverted ideas of patriotism. A painful example of this occurred the other day when two rival schools of Tropical Medicine amused the readers of the medical papers by their controversy as to the original discoverer of a quite unimportant parasite, the truth being that the credit belonged to neither of them, but to a foreign observer. Again, we have noticed that in the publications of certain schools, reference to any work done elsewhere is often entirely lacking. In view of such a condition of affairs, the thanks of all disinterested people are due to Professor Osler for his courageous and frank address with the above title to the Canadian Medical Association. With that eloquence which belongs but to few, he shows that science is one, and not the property of any nation; that her cult is not narrow, and that nationalism, provincialism, and parochialism are hindrances, not helps, to her worship.

The Influence of Treatment on the Tertiary Stage of Syphilis.

IT is generally believed that the liability to severe tertiary symptoms after an attack of syphilis is greatly modified by adequate mercurial treatment during the primary stage. That this should be the case is only what one would expect in view of the remarkable influence of the treatment on the earlier manifestations, but statistical evidence of the fact must necessarily be extremely difficult to procure, especially as other factors, such as alcoholism, undernutrition, and a weakly constitution, probably exert an influence on the production of these later lesions. Dr. Weber, of Berne, has tabulated the statistics of 185 cases of tertiary syphilis in hospital patients and 49 in private practice. Of the former class 77·3, and 40 8 of the latter had not undergone any treatment. Investigating cases of syphilis from another point of view he found that 51, or 34·7 per cent., of 147 private patients at all stages of the disease, who had undergone either an inadequate course of treatment, or none at all, developed tertiary symptoms, while only 13, or 5 per cent., of 261 patients who had undergone more than one course of treatment suffered in this way. There is consequently a marked difference between the two classes of cases, a difference which, allowing for the influence of other factors, militates strongly in favour of the effect of proper treatment in averting the later manifestations of syphilis.

Medical Practice in Spain.

Since 1868, foreign practitioners desirous of exercising their calling in Spain have been accorded very great facilities, the recognition of equivalence and the grant of the right to practise having been left in the hands of the medical faculties. This latitude, it seems, has given rise to considerable abuse, at any rate that is the reason alleged by the Government for withdrawing the right of granting dispensations and permits from the universities and vesting them *de novo* in the State. All existing licences to practise granted to persons not possessed of a Spanish diploma will be held to have expired six years hence, dating from November 9th, 1902. In future, only temporary permits will be conceded, and these only at the instance of the Government and with the approval of the General Council of Education.

The Lord Lieutenant of Ireland has intimated his intention of conferring the honour of Knighthood upon Mr. Charles B. Ball, M.D., who, it will be remembered, successfully operated upon Lady Dudley when she was suffering from appendicitis.

Correspondence.

[We do not hold ourselves responsible for the opinions of correspondents].

CORONERS' COURTS AND MEDICAL EVIDENCE.

To the Editor of The Medical Press and Circular.

Sir,—The attention of members of the honorary medical staffs of hospitals may well be drawn to the necessity of their attendance when called to give evidence at inquests. Recently several instances have come under my notice where honorary surgeons have actually ignored the summons to attend an inquiry into the cause of death of a hospital patient. Their evidence was required in deaths under anæsthetics, a class of case in which clearly the public has the right to demand the most skilled evidence that can be procured. In one such inquiry a well-known hospital surgeon protested against his being called as a witness. He said that his attendance caused him *the greatest inconvenience and a considerable loss of fees*, as if public duty did not lay a similar tax upon the resources of the ordinary citizen. At the same time, he was compelled to admit that the deceased patient died whilst undergoing an operation at his hands. He contended, however, that a house surgeon could have given all the necessary evidence. The sooner the minds of honorary hospital surgeons and physicians are disabused of that kind of arrogance the better for the community. The humanity and general good sense of the gentlemen in question is universally recognised, and it would be a thousand pities were they to be marred by want of a little timely consideration.

I am, Sir, yours truly,
General Practitioner.

OBSTRUCTIVE DYSMENORRHŒA.

To the Editor of The Medical Press and Circular.

Sir.—I am obliged to Dr. Herman for his notice of my remarks on above subject in The Medical Press of December 10th, and for his reply to my question.

I am, however, surprised that he did not publish the effects obtained in the one case of dilatation which he is evidently surprised at ("lasting for over twenty years"), in his paper in the *British Medical Journal*.

Most gynæcologists have met with one case of the kind; one case proves nothing. What about the lasting effect in the other cases treated?

Dr. Herman's sweeping condemnation of all stems is, I am glad to say, not shared in by most gynæcologists. There are stems and stems, and his statement that "many deaths have been caused by them" needs confirmation. Again, Dr. Herman states "no one has yet published a plain account of a series of cases treated with intra-uterine stems; then may I ask on what grounds he makes the previous statement quoted, "Many deaths, &c."? My stem differs entirely from those "in use for half a century" (wonder is they still survive!).

Mine are flexible, the old form rigid; mine are hollow, the old form solid; they were not self-retaining, mine are; they are shorter than uterus, the old form often were too long. They are hinged at base, and, with the flexibility combined, yield to every movement of uterus, and I have had no deaths or chronic invalids as a result of their use—now extending over ten years.

I also think I have had quite sufficient experience to diagnose endometritis from " " Whites " (vaginal leucorrhœa).

The intra-uterine stems he alludes to were not of my design; he has never tried them, and yet includes them in the universal condemnation! Is it fair to condemn what has not been tried?

If Dr. Herman knows "that an intra-uterine stem is an efficient cause of endometritis," I hope the information is not second-hand. As I have found my stems not only cure the endometritis but the dysmenorrhœa as well owing to their action as drainage tubes.

Dr. Herman's statement that divaricating dilators "tear instead of stretching" depends altogether on who uses the dilator, and is probably founded on his own unfortunate experience, for the same reason that "a burnt child dreads the fire, 'therefore' he uses them not"

Dr. Herman's argument "that what we want is not new instruments" or new drugs (Sydenham), would imply a perfect knowledge of those at his disposal, and on the same principle we want no motor-cars or locomotive engines, the stage coach or omnibus (properly driven) being good enough.

I am, Sir, yours truly,
Alexander Duke.

London, W., December 29th, 1902.

Literature.

POLITZER'S TEXT-BOOK OF EAR DISEASES. (a)

It is eight years since the last edition of this widely known work on Diseases of the Ear appeared. Since then many important additions, pathological and clinical, have been made in otological science. That these advances have been fairly noted in the comprehensive volume before us is evidenced by the fact that the older edition has been increased by over one hundred very closely printed pages. The whole work bears evidence of complete revision, and those departments of otology in which the greatest study has been made, are in great measure rewritten. The translation of the veteran otologist's manuscript has been carried out by Drs. Milton Ballin and Clarence Heller, to whom the author pays the merited compliment of saying that "the book does not read like a translation, but more like an original work." He adds that they have done the difficult task "splendidly." English readers will endorse this approval, for we have seldom seen a translation from the German which betrays fewer traces of the translators' difficulties than this does. This may partly be explained by the fact that the translation was carried out in Vienna under the direct personal supervision of the author. And it would be ungenerous not to acknowledge here, as the translators do, how faithfully Mr. Charles L. Taylor (London) has dealt with the not least important part of a translation, viz., the supervision of the pages in their passage through the Press.

(a) "A Text-Book of the Diseases of the Ear." By Professor Dr. Adam Politzer, of Vienna. Translated and Edited by Milton Ballin, Ph.D., M.D. and Clarence L. Heller, M.D Fourth Edition revised and enlarged. 884 Pp. 346 illustrations. Price 25s. London. Bailliere, Tindall, and Cox. 1902.

In the short space at our disposal we can only refer generally to the work, which covers not only the whole field of practical otology, but comprises also a complete description, in the fullest sense of the word, of the anatomy and physiology of the ear. Many of the excellent original drawings which illustrate the latter portions of the book are already well known. We suppose that there is no living otologist who can draw on such rich and almost inexhaustible material as Professor Politzer, as those who have seen his private collection of preparations, anatomical and pathological, will understand. Sixty pages at the commencement of the work are devoted to the anatomy and physiology of the external and middle ear, and later on, before discussing the diseases of the internal ear, twenty-eight pages are given up to the "Anatomy and Physiology of the sound-receiving apparatus." Ninety-four pages are devoted to methods of examination, with general remarks on treatment, and a full analysis of the various modes of testing the hearing. We miss here a description of Edelmann's Galton-pipe, which is the most perfect instrument for registering the vibrations of high tones, enabling us with perfect accuracy to differentiate and determine the hearing power in both ears for these. In sixty-six pages the affections of the external ear are dealt with, while 429 are absorbed by the diseases of the middle ear, including all the secondary mastoid, cranial, and intra-cranial complications of its suppurative states.

It is to this part of the work that the aural specialist and the general surgeon will turn with the greatest interest, and we are bound to say that it is here the fullest reward will be found. Clearly and lucidly are all the most recent advances in our knowledge of the pathological sequences of middle-ear disease discussed, and the advantages relatively of the various operative procedures proposed for their relief pointed out, while the operative steps are lucidly explained in detail. This section is the most striking portion of the new edition. On pages 535-538 are categorically set out the various objective and subjective signs and symptoms which indicate the necessity for a radical operation in chronic, persistent, middle-ear suppuration. This summary, coming from such an authoritative source and from such a school as Vienna, is worthy of the most thoughtful perusal of every otologist and practitioner who bears the responsibility of the conduct of a case of obstinate suppurative middle-ear inflammation with its varying complications. These are the questions many able surgeons are asking: Are the number of radical operations we now read and hear of justified by the urgency or severity of the symptoms? Are the ultimate and permanent results exactly recorded? Are the disadvantages of the radical treatment fairly balanced side by side with the advantages of careful, methodical, and sustained curative and conservative methods? Are the vaunted "cures" in a considerable proportion of radical operations (*sic*) unsatisfactory, followed by deterioration of hearing, continued discharge, some facial paralysis, or a protracted convalescence, and often necessitating a second grafting or other operation? The boom of "radical" operations has been so great that no young otologist considers himself worthy of the name if he cannot boast of having performed some hundreds of these, and his prowess is further shown by the exhibition of an internal ear which his zeal has prompted him to remove. There is no question of the justification for these operations under certain circumstances, in the face of symptoms which call for urgency, or when the chronicity of the disease and the pathological signs demand them. But we have serious misgivings whether by this comparatively recent departure in the therapeutics of otology we are not being led away from safer and sounder methods of treatment, though perchance not as showy or gratifying to the ambitious surgeon. We are not alone in this view, and very much doubt if the pendulum will not swing in the other direction before long, and the number of "radical" operations become increasingly less. Professor Politzer's conclusions on this subject are worthy of notice

He says:—"In all cases of persistent middle ear suppuration in which the objective and subjective symptoms, so paramount for the operation, are lacking, we must confine ourselves to the conservative treatment, and in cases in which the indications are not urgent, an endeavour should always be made to control the suppuration by a thorough local treatment before deciding upon operative procedures."

We most cordially endorse these prudent reservations of the author. Of the remaining chapters of this exhaustive treatise, seventy-seven pages are occupied by a discussion of the diseases of the naso-pharynx and the accessory sinuses of the nose, with reference to diseases of the middle ear. This includes the treatment of adenoid vegetations.

Diseases of the internal ear, which are most thoroughly dealt with, and such practical questions as signal deafness in railway employeés, malingering, cerebral disturbances of hearing, malformations, and deaf mutism, complete this most valuable addition to otological literature, which, although primarily intended for the special surgeon rather than the practitioner, no otological specialist's library can be complete without this comprehensive compendium contributed by a master hand.

A MANUAL OF MEDICAL TREATMENT. (a)

The first edition of this most valuable book made its appearance in 1893. Who can refrain from pitying an author who conscientiously tries to weigh the relative merits and estimate the utility of the thousands of therapeutic agents invented since that date? Dr. Burney Yeo, in this new and revised edition of his manual, has saved himself much trouble by strictly adhering to clinical therapeutics, merely giving his readers the benefit of his own large clinical experience, and that of equally respectable authorities. For this reason the book is an eminently practical one, all theoretical discussions concerning the chemical constitution and physiological action of drugs being left severely alone. It is a book from which the most skilled therapeutist has something to learn, a book which the more ordinary physician, no matter how frequent his appeals to it, will surely find a true guide, philosopher, and friend. One thought at the time that improvement on the first edition would be next to impossible. Success, however, is a wonderful stimulant to an author, hence we have a thoroughly revised, extended, and modernised edition of the "Manual of Medical Therapeutics" which is likely to remain, for some time to come, the standard work on the subject in the English language. We feel at liberty to give the book unqualified praise, and almost constrained, not only to recommend it, but also to urge it upon all who do not possess it, yet are ambitious of becoming polished practical physicians.

(a) "A Manual of Medical Treatment." By J. Burney Yeo, M.D., F.R.C.P., Emeritus Professor of Medicine in King's College, London; Consulting Physician to King's College Hospital; Hon. Fellow of King's College, formerly Professor of the Principles and Practice of Medicine and of Clinical Therapeutics in King's College, and Examiner in Medicine at the Royal College of Physicians. Author of "Food in Health and Disease," &c., &c. New and Revised Edition. 1902. Vol. I., pp. 696. Vol. II., pp. 818. Two Vols., price 21s. London: Cassell and Company, Ltd.

THE PRACTITIONER'S GUIDE. (*a*)

This book, from many points of view, is truly useful as a practitioner's guide. It is arranged in dictionary form, so that reference is easy. In addition a careful index has been compiled, which further facilitates reference by giving the synonyms of the subjects arranged in alphabetical order in the text. The chief claim of this work to the name "guide" is undoubtedly the concise, practical, and intelligible manner in which the subjects are treated, more particularly concerning differential diagnosis and treatment. It embraces all the subjects that any general practitioner requires to know except midwifery, which the authors consider so important that they realised the hopelessness of attempting to deal with it efficiently while keeping the volume of convenient size. Tropical diseases are most admirably done, with all due consideration to modern discoveries. Surgical operations are not described, other than those which may, with propriety, be undertaken by the general practitioner. Gynæcology receives a lion's share of attention, yet, considering the amount of information imparted, the subject is handled with masterful brevity. The general medicine and surgery is good, concise and practical.

We have no hesitation whatever in recommending "The Practitioners' Guide" to those for whom it was intended. No general practitioner need feel ashamed of the stock of medical knowledge he could readily acquire were he merely to read the pithy accounts in this book of the diseases which come under his notice. The publishers are to be congratulated on the appearance, printing, and binding of the volume.

Literary Notes and Gossip.

The January number of the *Westminster Review* contains, among a number of good articles, a remarkable one on "Insanity." The facts herein grouped, although frequently commented on in our reviews of asylum work, are so appalling when brought together in a collected form, that they will naturally suggest to the reader whether something cannot be done to arrest the spread of the disease. The special feature of the *Review*, viz., the sections on Contemporary Literature, including those on Science, Philosophy, Belles Lettres, &c., are well worth reading.

⁂

The "Reuben Harvey" Memorial Prize, which is given triennially by the Royal Colleges of Physicians and Surgeons of Ireland for the best essay on some subject evidencing original research in animal physiology and pathology, will be awarded on July 1st, 1903. The prize consists of £25, and the competition is open to all students of medical schools recognised by the Colleges, and also to all licentiates and graduates of not more than three years' standing. The competing essays must be lodged with either of the Registrars of the Colleges before June 1st, 1903.

⁂

This "Life of St. Luke," by Edward Clapton, M.D. (Churchill), is written in a simple but intelligent way. This life of the beloved physician will be interesting to all, but especially to the medical world. It brings out in a striking way the force, the sweetness, the refined intellectuality of him who, next to the Great Physician, must ever rank as the noblest of his class. So little is known about this great apostle that it is interesting to have all the details obtainable, both from the Bible and elsewhere, collected together, and put into readable form, and it is of particular value and interest, since the collection is made by one who is himself a physician. It may be recommended to all who wish to know more of the life and work of St. Luke.

⁂

Who's Who for 1903 has made its appearance with the punctuality characteristic of the best class of annuals to which this undoubtedly belongs; and from a casual reference to pages here and there, the publishers, Messrs. A. and C. Black, appear to have done the revision and additions with great accuracy. Many of the biographies are interesting reading, albeit those of leading members of the medical profession may provoke comment. Of course the work is not a directory in any sense. To take it out of this category, no addresses are given. It is simply what its title expresses, and as such is probably unique. The same publishers have sent us also "The Englishwoman's Year-book" for 1903, which might be aptly described as an educational, professional, and industrial guide for girls and women, and as such will be found useful to the large number who are always seeking for hints or guidance.

⁂

Those of our readers who are interested in asylum work may remember a small magazine which made its appearance a few years ago with the title of "Loose Leaves," under the editorship of the late Mr. Hyslop, its contributors being the staff and patients of the Church Stretton Private Lunatic Asylum. It was a bright, merry little publication, full of quips and moonstruck foibles for "laughter of the gods." With the death of its founder the magazine ceased to appear, but has started afresh this week, its writers "gloating in their literary and legal irresponsibility" in the same amusing and fantastic fashion as of yore. The editor invites contributions from outsiders, who need not be responsible for their opinions or their grammar, and we join him in wishing that this little effort to direct and divert the minds of asylum patients may have a long and prosperous career.

⁂

It is interesting to note how often in recent biographies and "reminiscences" references to medical men occupy a prominent place. This is conspicuous in the most charming "Random Reminiscences" of Mr. Charles H. E. Brookfield, recently published. On one occasion the author got into a railway carriage at Southampton, in which was seated Sir William Jenner, returning from a visit to Osborne, and the latter described how once in student days he started to go to the pit of the old Haymarket Theatre in order to get a glimpse of the Queen and the Prince Consort. The crush was immense, and in the struggle Jenner's coat was torn in twain from tails to the collar. Returning home in high dudgeon the sufferer exclaimed to himself, "I'm d——d if I'll ever go and see the Queen again." "Which only shows," added Sir William with a humorous twinkle, "that one ought not to speak without knowing."

⁂

DIARIES AND ALMANACS.

The appearance of that hardy annual, "Whitaker's Almanack for 1903," bids us prepare to take leave of 1902. Every precaution has been taken to avert the obesity which is the curse of old age—in works of reference as in human beings—and although the present volume is decidedly portly compared with its inaugural issue, it is within becoming limits. There are signs, too, that it has attained what we may call its "physiological weight," for the annual increment for some years past has been extremely moderate—this year only six-

---

(*a*) "The Practitioner's Guide.' By J. Walter Carr, M.D.Lond., F.R.C.P., Physician to Royal Free Hospital, Physician to Victoria Hospital for Children, Joint Lecturer on Medicine London (Royal Free Hospital) School of Medicine for Women; T. Pickering Pick, F.R.C.S., Consulting Surgeon to St. George's Hospital and Victoria Hospital for Children; Alban H. G. Doran, F.R.C.S., Surgeon to the Samaritan Free Hospital; Andrew Duncan, M.D., B.S.Lond., F.R.C.S., M.R.C.P., Physician Branch Hospital Seamen's Hospital Society, Joint Lecturer on Tropical Medicine at London School of Tropical Medicine, Physician Westminster Dispensary, Fellow of King's College, London. In one Vol. Pages 1,106. London: Longmans, Green and Co.

teen pages—which is almost a *quantite negligeable* in a volume of close upon 800 pages. The promotions and appointments gazetted during the year in connection with the war and the Coronation occupy a large share of the extra space, and much revision has been necessitated by the "linking up of the Empire." Valuable chapters are devoted to such current topics as the Education Bill, the Temperance Problem, Wireless Telegraphy, &c. In short, the volume for 1903 displays the same enterprise and accuracy which have gained for it public favour in the past.

"Knowledge Diary and Scientific Handbook for 1903" should find a welcome among many medical men who do not confine their scientific pursuits merely to professional purposes. In addition to a plentiful diary allowance of space, a page being granted for each day, there is much miscellaneous information peculiarly useful to scientific men. There are also original descriptive articles on the spectroscope, the choice of a microscope, observation of variable stars, meteorological observations and monthly astronomical ephemera. The paths of the principal planets for the year are well illustrated with charts, and twelve star maps show the night sky for every month in the year with descriptions of the visible constellations and principal stars. There are also many useful tables of reference dealing with matters of Imperial interest and lists of the principal scientific and learned societies and principal London clubs. The work reflects high credit on all concerned in its production. We strongly commend this diary to our readers, and especially to those interested in astronomy.

THE MEDICAL DIRECTORY FOR 1903.

The New Medical Directory has been issued with commendable punctuality, that for the New Year being already in our hands. Those who have been accustomed in past years to refer to the bulky volume, which annually increased in unwieldiness, will scarcely recognise the new comer. The publishers (Messrs J. and A. Churchill) appear to have recast the entire production, and although it may not commend itself to the conservative tendencies of everyone, we consider the alterations are decided improvements, and that as a work of reference it will be found much more convenient. The change which will attract most attention is the increased size of the page from a demy to a royal octavo, which materially reduces the thickness of the volume, and enables one to keep it open at any given page more readily. The typography and binding have also been improved, and we congratulate the publishers on their enterprise.

NEW BOOKS AND NEW EDITIONS.

The following have been received since the publication of our last list:—

Baillière, Tindall and Cox (London).

Points of Practical Interest in Gynæcology. By H. Macnaughton-Jones, M.D., M.Ch., Q.U.I. Third Edition with 24 plates. Pp. 188. 4s. 6d. net.

Aids to Gynæcology. By Alfred S. Gubb, M.D. (Paris), M.R.C.S.Eng. Fourth Edition. Pp. 136. Price 2s. 6d.

Aids to Forensic Medicine and Toxicology. By William Murrell, M.D., F.R.C.P. Sixth Edition. Price 2s. 6d.

Modern Microscopy. By M. J. Cross and Martin J. Cole. Third Edition. Pp. 292. Price 4s. net.

Constipation. By Sherman Bigg, F.R.C.S.E. Pp. 67. Crown 8vo. Price 2s. 6d. net.

A. and C. Black (London).

Who's Who, 1903. An Annual Biographical Dictionary. Pp. 1532. Price 5s. net.

The Englishwoman's Year Book and Directory. 1903. Edited by Emil Janes. Pp. 340. Price 2s. 6d. net.

J. and A. Churchill (London).

Second Treatise on the Effects of Borax and Boric Acid on the Human System. By Dr. Oscar Liebriech. Pp. 87. Price 2s. 6d.

Cancer and other Tumours of the Stomach. By Samuel Fenwick, M.D., L.R.C.P., and W. Soltau Fenwick, M.D.Lond., M.R.C.P. Pp. 362. Price 10s. 6d.

Reports of the Society for the Study of Diseases in Children Vol. II., season of 1901-1902. Edited by George Carpenter. M.D. Pp. 310. Price 12s. 6d.

Year-Book of Pharmacy and Transactions of the Brit. Pharm. Conf. 1902. Pp. 566.

H. K. Lewis (London).

The Etiology of Typhoid Fever and its Prevention; being the Milroy Lectures delivered at the Royal College of Physicians in 1902. By W. H. Corfield, M.A., M.D. Oxon. Pp. 159. Price 2s. 6d.

The Office of the "Mark Lane Express" (London).

The Agricultural Annual and Mark Lane Express Almanac, 1903. Pp. 184. Price 6d.

W. B. Saunders and Co. (Philadelphia and London).

Atlas and Epitome of Traumatic Fractures and Dislocations By Prof D. H. Helferich. Edited by Joseph C. Bloodgood M.D Fifth Edition, revised and enlarged. Illustrated. Pp. 353. Price 13s. net.

Treatment of Fractures. By Charles L. Scudder, M.D. Third Editon. Illustrated. Pp. 450. Price 19s. net.

A Text-Book of Obstetrics. Two vols. By Richard C. Norris, M.D., and Robert L. Dickinson. M.D. Pp. 600. Price 35s. net

The Scientific Press, Ltd. (London).

The Nursing Profession: How and Where to Train. Edited by Sir Henry Burdett, K.C.B. Pp. 373. Price 2s. net.

John Wright and Co. (Bristol).

Our Baby: for Mothers and Nurses. By Mrs. J. Langton Hewer Eighth Edition, revised. Pp. 154. Price 1s. 6d. paper, 2s. 6d. cloth. Pp. 154.

J. Whitaker and Sons, Ltd. (London).

Whitaker's Peerage, 1903; being a Dictionary of Titled Persons Pp. 703.

Whitaker's Almanack, 1903. Pp. 792. Price s. 6d. net.

Medical News.

University of London.

The following three courses of lectures on Advanced Physiology will be delivered in the Physiological Laboratory at the university during the ensuing spring term, commencing on Tuesday, January 20th, at 5 p.m.:—

(*a*) "On the Chemistry of Muscle and Nerve," by W. D. Halliburton, M.D., F.R.S., Professor of Physiology at King's College, on Tuesdays, January 20th, 27th; February 3rd, 10th, 17th 24th; March 3rd, 10th, at 5 p.m.

(*b*) "On the Circulation," by T. G. Brodie, M.D., Lecturer on Physiology at the London School of Medicine for Women, on Thursdays, January 22nd, 29th; February 5th, 12th, 19th, 26th; March 5th, 12th, at 5 p.m.

(*c*) "On the Action of Anæsthetics and Narcotics," by A. D Waller, M D., F R S, Lecturer on Physiology at St. Mary's Hospital. on Fridays, January 23rd, 30th; February 6th, 13th, 20th, 27th; March 6th, 13th, at 5 p.m.

The lectures are addressed to advanced students, and arranged to meet the requirements of candidates for honours in physiology at the university.

The Scholarships and Medals at the B.Sc. Examination, October, 1902, and the M.B. and Examination November, 1902, have been awarded as follows:—

The University Scholarship in Botany – Stafford Edwin Chandler (Royal College of Science and private study).

The University Scholarship in Physiology.—John Molyneux Hamill (Trinity College, Cambridge, and St. Bartholomew's Hospital).

The University Scholarship and a Gold Medal in Medicine.—Robert Pugh Rowlands (Guy's Hospital).

A Gold Medal in Medicine.—Alexander Cameron (Middlesex Hospital).

The University Scholarship and a Gold Medal in Obstetric Medicine. Ernest Rock Carling (Westminster Hospital).

A Gold Medal in Obstetric Medicine.—Lucian Arnold Emmanuel de Zilwa.—(University College and Ecole de Médicine, Paris).

The University Scholarship and a Gold Medal in Forensic Medicine.—Harold Edward Ridewood (London Hospital).

A Gold Medal in Forensic Medicine.—Frank Blenkinsopp Skerrett (St. Thomas' Hospital).

Egyptian Congress of Medicine.

The inaugural ceremony in connection with this Congress, by His Highness the Khedive, took place on December 15th, when Mr. Reginald Harrison, F.R.C.S., as delegate of the Royal College of Surgeons of England and the representative of Great Britain and Ireland, addressing his Highness, offered on behalf of his countrymen engaged in the practice of medicine their most respectful congratulations and thanks on the occasion. It was, he remarked, a matter of regret that Great Britain should not be more fully represented, but at this time of the year many distinguished and well known members of the profession at home have professional duties to perform, which rendered their presence in Egypt impossible. In initiating this Congress and extending to it his personal patronage, the profession were deeply sensible of the desire of his Highness not only to promote the health and prosperity of his own subjects, but to encourage, for the advantage of humanity generally, independent research in that ancient and historical country. On the subject of education Mr. Harrison added that, by the direction of his college, it had been his duty and pleasure to look into the system and methods of medical education and examination employed for enabling young Egyptians and others to learn and to practise medicine and surgery, under diploma in Egypt, and having made himself acquainted from personal observation with the Hospital and School of Medicine in Cairo, where such instruction is, and has been, systematically given, the marked efficiency and progressive character of these institutions had surpassed his anticipations.

Royal Army Medical Corps.

The Secretary of State for India has approved an increase of the pay of officers of the Royal Army Medical Corps serving in India. This increase is in the same ratio as the recent increase in the pay of officers of that corps serving at home. The rates will be as follows:—Lieutenant, Rs.420 *per mensem*; captain, Rs.475; over seven years' service, Rs 530: over ten years' service, Rs.650 Charge allowance: hospital of 300 beds, Rs.240 *per mensem*; hospital of 200 beds, Rs.180; hospital of 100 beds, Rs.120; hospital of 50 beds, Rs.60. Specialist pay at the rate of Rs.60 *per mensem* has also been sanctioned.

Deaths from Chloroform.

A young man succumbed to chloroform narcosis at the Barrow Hospital on the 22nd inst., prior to an operation. No details as to the quantity of chloroform used or the method of administration were elicited, and the stereotyped verdict was returned. A similar catastrophe at St. Bartholomew's Hospital was inquired into on the same day, but in this case the patient, a man, æt. 48, was undergoing removal of the upper jaw for cancer, so that the death may be classed as one of those which happen while under chloroform without any necessary connection with the action of the anæsthetic.

Pass Lists.

University of Cambridge

At the examinations for medical and surgical degrees, Michaelmas term, the following candidates were successful:—

First Examination.

Part I.—Chemistry and Physics: L. T. Baker, Sidney Sussex; M. E. Balston and A. Barker, Trinity; D. C. Bluett, Emmanuel; A. F. Burton, B.A., Christ's; R. S. Carey, Corpus Christi; R. G. Chase and G. G. Collet, Trinity; B. Day, B.A., Caius; M. Donaldson, Trinity; G. W. Dryland, H. L. Duke, T. G. Elger, and H. B. Elton, Caius; E. G. Fearnsides, Trinity Hall; W. J. Fison, Sidney Sussex; P. Hamill, Trinity; A. Hamilton, Christ's; H. A. Harris, Emmanuel: C. B. Heald, Caius; E. H. V. Hodge, Clare; A. F. Jackson, Peterhouse; L. R. King, Pembroke; A. H. Lees, King's; H. M. J. F. de P. P. Leite, Caius; F. H. Lester, Pembroke; C. K. McKerrow, Clare; A. J. May, Sidney Sussex; E. Mellanby, Emmanuel; R. M. Moore, St. John's; E. E. Paget-Tomlinson, Trinity Hall; B. H. Palmer, Pembroke: F. N. Pethick, Trinity; K. Pretty, King's; A. L. Sachs, M.A, Pembroke; K. J. Saunders, Emmanuel; C. F. Searle, Pembroke; S. E. T. Shann, Caius; R. M. Soames, Trinity; A. E. Stansfield, St. John's; A. C. Sturdy, Pembroke; F. H. Teall, Sidney Sussex; A. K. Toulmin-Smith, B.A., Emmanuel; C. H. Treadgold, Clare; G. W. Twigg, Caius; R. P. Varwell, St. John's; P. J. Verrall, Trinity; T. A. Weston, St. John's; C. Whitaker, B.A., Emmanuel; and R. Gregson Williams and P. F. Wilson, Caius.

Part II.—Elementary Biology: C. A. Anderson, Downing; F. W. Argyle, St John's; L. T. Baker, Sidney Sussex; A. Barker, Trinity; W. N. Child and H. N. Coleman, Christ's; J. P. H. Davies and A. P. Denby, Jesus; H. L. Duke and T. G. Elger, Caius; E. G. Fearnsides, Trinity Hall; E. G. Fisher, Emmanuel; W. J. Fison, Sidney Sussex; T. S. Gibson, Emmanuel: P. Hamill and W. Harmens, Trinity; C. B. Herald, Caius; E. H. V. Hodge, Clare; J. W. Horne, B.A., Pembroke; S. W. Howard, Trinity; H. E. Humphrys, Caius; A. F. Jackson, Peterhouse; R. Knowles, Downing; A. H. Lees, King's; L. F. G. Lewis, Christ's; C. K. McKerrow, Clare; A. G. M. Mainwaring, Trinity; W. Mathieson and A. J. May, Sidney Sussex; R. M. Moore, St. John's; J. D. Morgan, B.A., and M. W. B. Oliver, Trinity; K. Pretty, King's; E. L. N. Rhodes, H. Selwyn, K. J. Saunders, Emmanuel; A. E. Stansfeld, St. John's; A. C. Sturdy, Pembroke; F. H. Teall, Sidney Sussex; A. K. Toulmin-Smith, B.A., Emmanuel; W. W. Treve and G. W. Twigg, Caius; R. W. S. Walker and H. P. Weaver, B.A., Trinity; T. A. Weston, St. John's; H. B. Wilson, Pembroke; W. B. Wood, Jesus; and M. M. Woods, Clare.

Third Examination.

Part I.—Pharmacology and General Pathology: H. Ackroyd, B.A., Caius; C. E. A. Armitage, B.A., Emmanuel; H. M. Aviss, B.A., Downing; E. Bell, B.A., Clare; G. F. Bird, B.A., Trinity; E. M. Browne, B.A., Pembroke; H. A. Browning, B.A., St. John's; M. A. Cassidy, B.A., Clare; S. H. Clarke, B.A., Caius; R. M. Courtauld, B.A., Pembroke; G. H. U. Corbett, B.A., and G. Cowan, B.A., Kings; W. B. Crowfoot, B.A., Emmanuel; C. R. Crowther, B.A., St. John's; C. W. Cunnington, B.A., Non-Collegiate; H. M. Davies, B.A., Trinity; H. S. Dickson, B.A., Christ's; J. H. Donnell, B.A., Caius; T. L. Drapes, B.A., Sidney Sussex; T. Drysdale, B.A., Jesus; R. G. Elwell, B.A., Trinity; A. H. Falkner, Peterhouse; T. J. Faulder, M.A., Clare; H. H. J. Fawcett, B.A., Trinity; N. Corbet Fletcher, B.A., F. M. Gardner-Medwin, B.A., Trinity: J. Goss, B.A., Jesus; G. S. Haynes, King's; F. A. Hepworth, B.A., St. John's; W. R. Higgins, B.A., Caius; E. Higson, B.A., Magdalene; T. W. S. Hills, B.A., Downing; G. Holroyd, B.A., Christ's; H. F. Horne, B.A., and W. G. Howarth, B.A., Kings; J. B. Irving, B.A., St John's; H. M. Joseph, B.A., Trinity; J. Lambert, B.A., Down.; J. C. Lawton-Roberts, B.A., Clare; F. F. Leighton, B.A., St. John's; S. M. Mackenzie, B.A., Trinity; M. McPherson, B.A., Clare; H. Marris, B.A., Caius; O. May, B.A., St. John's; W. M. Mollison, B.A., King's; A. R. Moore, B.A., Caius; R. F. Moore, B.A. Christ's; W. L. Murphy, B.A., St. John's; C. M. Murray, M.A., Pembroke; W. V. Naish, B.A., Emmanuel; L. Noon, B.A., Trinity; J. A. A. Orlebar, Magdalene; C. E. Palmer, B.A., Caius; W. H. Rayner, B.A., H. Rischbieth, M.A., and J. C. Rix, B.A., Trinity; N. O. Roberts, M.A., Christ's; H. Robinson, B.A., Trinity; J. G. Slade, M.A., Clare; T. D. Smith, M.A., Jesus; C. Stiebel, Trinity Hall.; R. S. Taylor, B.A., Down.; F. J. Thornton, B.A., and W. H. Thresher, B.A., Caius; F. C. Trapnell, B.A., King's; A. W. Wakefield, B.A., Trinity: E. Ward, B.A., Clare; J. D. C. White, M.A., and L. E. Wigram, B.A., Trinity; A. Wilkin, B.A. and E. K. William, B.A., Caius.

Notices to Correspondents, Short Letters, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

CLIPPINGS FROM LAY EXCHANGES.

ICELANDIC CANINOPATHY.

"J—— W——, a patient at the Holy Cross Hospital, died yesterday. . . . Dr. —— finally reached the conclusion that the patient's disease was echinococcus peculiar to Iceland, and superinduced by association with dogs."—*Salt Lake* (Utah) *Tribune.*

MISSIONARIES NEEDED IN NEWPORT.

"Dr. —— of ——, Ind., died at 12.5 a.m. last Sunday, May 11th, 1902, in Terre Haute, from effects of a surgical operation for fistula in ano. About nine-tenths of the surgical operations of the present day result in death."—*Newport* (Ind.) *State.*

A. THOMSON.—It was impossible to have made a forecast of the result.

MR. ASHLEY BITTEN.—We cannot give the name of a consultant. The practitioner in attendance should be asked to do so.

B. B.—Our correspondent should return the cheque to the solicitors and state his claim for higher fees.

DEDICATED TO MEDICALS WITH MORE LUCK THAN BRAINS. SOMETIMES MET WITH IN CONSULTATION.

He couldn't pass a catheter,
He couldn't "sound for stone,"
He couldn't "put a fracture up,"
Or set a broken bone.

He couldn't "tap a hydrocele,"
Or bandage up a limb;
He couldn't work the microscope,
It was too much for him.

He couldn't "cup," he couldn't bleed,
And it would make you laugh
To see him try to "draw a tooth,"
Or use the "sphymograph."

In spite of all his ignorance,
His manner is so bland;
He humbugs all the public,
And he drives a four-in-hand.

. . . . .

The moral to be drawn from this
Is very plain to see,
You want no skill with people ill
To make the £ *s. d.*

A. D.

Meetings of the Societies, &c.

LONDON.

THURSDAY, JANUARY 1ST.

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle Street, W.).—3 p.m. Prof. H. S. Hele-Shaw: On Locomotion, on the Earth, through the Water, in the Air. (Christmas Lectures adapted for Young People.)

ANÆSTHETICS, ANCIENT AND MODERN,

their Physiological Action, Therapeutic Use, and Mode of Administration; together with an Historical Résumé of the Introduction of Modern Anæsthetics; and also an account of the more celebrated Anæsthetics in Use from the earliest time to the discovery of Nitrous Oxide.

By GEORGE FOY, F.R.C.S.

"Mr. Foy's work will ever remain classical in reference to the history of anæsthetics, practical in its directions as to the choice and manner of using them, and deserves a high position in the esteem of every surgeon."—*Virginia Medical Monthly,* Nov., 1889. "A really useful, interesting and instructive volume."—*Virginia Medical Monthly.* Dec., 1889. "Not only a valuable addition to the literature of anæsthesia, but it has a flavour of old-world learning and investigation that makes it most pleasant reading."—*Edinburgh Medical Journal,* April, 1890. "We congratulate the author on the industry, research, and learning which he has brought to bear upon his work, and we claim for him to have made a valuable and scholarly contribution to the literature of anæsthetics."—*Dublin Journal of Medical Science,* October, 1889.

London: Bailliere, Tindall & Cox, 8 Henrietta Street, Covent Garden.

THE ONLY ASEPTIC FEEDER MADE IS THE ROTUNDA FEEDING BOTTLE.

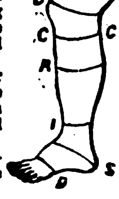
It is simple—only a pure rubber teat and bottle—no valve. It is safe—for it can be sterilised. It is cheap—6d.

Can be had wholesale from any Druggists Sundry House or from—

LEONARD & CO., CHEMISTS, DUBLIN.

Leonard's Rotunda Tissue, a superior Gamgee, 1/- per lb. Leonard's Clinical Thermometers 1/- each.

FOR Varicose Veins & Weakness, SURGICAL ELASTIC STOCKINGS



and **KNEE-CAPS,** pervious, light in texture, and **INEXPENSIVE,** yielding an efficient and unvarying support, under any temperature, without the trouble of Lacing or Bandaging. Likewise a strong low-priced article for Hospitals and the Working Classes.

ABDOMINAL SUPPORTING BELTS, those for Ladies' use, before and after accouchement, are admirably adapted for giving adequate support with **EXTREME LIGHTNESS**—a point hitherto little attended to.

Instructions for Measurements and prices on application, and the articles sent by post from the Manufacturers,

POPE & PLANTE,

Hosiers by appointment to the late Queen Victoria,
39B OLD BOND STREET, LONDON, W.
The Profession, Trade, and Hospitals are supplied.

The expedient of peptonising food is one of the most rational, scientific, and practical advances of modern medicine, and has been proved devoid of the slightest theoretical or discernible objection.

Panopepton

Presents the entire nutritive substance of prime lean beef and best wheat flour converted into a soluble, completely and freely assimilable form.

Panopepton

Is instantly and wholly assimilable and sterile.

Panopepton

Contains all the extractives, salts, and savory matters of the beef juice, which are of peculiar value as stimulants.

Panopepton

Contains all the proteids of the beef and wheat in a soluble non-coagulable form.

Panopepton

Is a complete food, containing the albuminoids, carbo-hydrates and phosphates—the flesh, fat, and bone making elements.

Schering's Formalin.

The Purest Product of 40 per cent. Formaldehyde, free from Metals and other Impurities. Suitable for physiological, antiseptic, antiputrefactive, and deodorant purposes, and for air sterilization in the sick-room.

Sold by all Chemists in 4 oz., 8 oz., and 1 lb. Bottles.

The Bottles are all labelled and capsuled by the Chemische Fabrik auf Aktien vormals E. SCHERING of Berlin, to which attention should be paid.

Room Disinfection.

The Modern Apparatus is in use with over 700 local authorities and Hospitals in this Country.

Glutol (according to Dr. Schleich.)

This Product, which is a chemical combination of Formalin Gelatine and forms a self-applying Antiseptic Bandage in THE TREATMENT OF WOUNDS, permits a continuous and penetrating disinfection of the surrounding tissues, without damage to the vitality or compensating power of the healthy body cells, thus favouring a speedy healing process.

GLUTOL (Schleich) is sold by all Chemists in 1 oz., 4 oz., and 1 lb. Tins.

With the label of the Chemische Fabrik auf Aktien v. E. SCHERING.

SOLE WHOLESALE AGENTS:

The Formalin Hygienic Company, Limited,

3 LLOYD'S AVENUE, LONDON, E.C.,

To whom all inquiries as to Literature, &c., should be addressed.

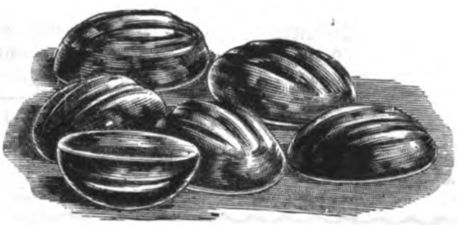
The "Allenburys"

Throat Pastilles.

SOFT. DEMULCENT. PALATABLE.

IN the medical treatment of most Throat Affections a simple and effective method of local application is a necessity. The exigencies of modern practice demand the employment of a large variety of drugs in a soothing and demulcent form.

THE Basis of the "ALLENBURYS" THROAT PASTILLES is composed of a special Pâte de Jujube which is soothing and palatable, while the local action of the drug incorporated, is made more certain by the slow rate of solution of the jujube in the saliva, than is the case with ordinary Lozenge or Pastille.



The following Pastilles are largely used, and have been found from long practical experience to be very efficacious :—

The "Allenburys" Pastille

No. 9. **Menthol, Cocaine, and Red Gum.**
Menthol, gr. 1/20th. Cocaine, gr. 1/20th. Red Gum, 2 grs.

No. 23. **Eucalyptus and Red Gum.**
Eucalyptus, ½ minim of the Oil. Red Gum, gr. i.

No. 28. **Compound Guaiacum.**
Guaiacum, gr. i. Chlorate of Potash, gr. ii. Red Gum, gr. ¾.

No. 29. **Compound Rhatany.**
Extract of Rhatany, gr. ii. Cocaine Hydrochl., gr. 1/20th

No. 38. **Chlorate of Potash, Borax, and Cocaine.**
Chlorate of Potash, gr. ii. Borax, gr. i. Cocaine, gr. 1/20th.

No. 54. **Menthol and Eucalyptus.**
Menthol, gr. 1/20th. Eucalyptus Oil, min. i.

CADBURY'S
COCOA

Is COCOA ONLY—not a combination of Drugs or a high-sounding alkalied article. As a refreshing, stimulating drink, and a nutritious food, CADBURY'S maintains its great superiority.

THE MEDICAL MAGAZINE says: "CADBURY'S is, without question, the favourite Cocoa of the day. For Nourishment, there is nothing superior to be found. ABSOLUTELY PURE, therefore BEST.

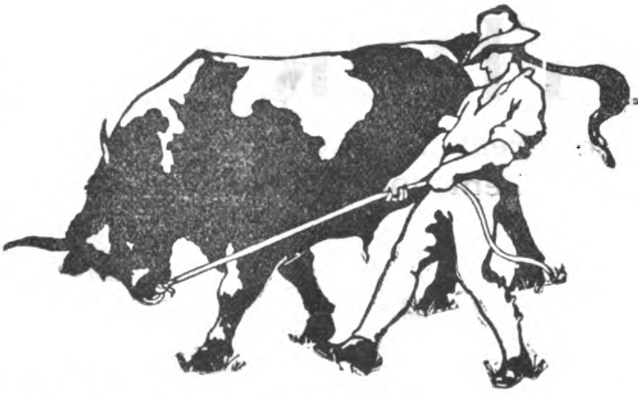
BRAND & CO., Ltd., Mayfair, London, W.



Liebig's Extract of Meat Company, Ltd.,

Established 1865.
Contractors to Hospitals, Infirmaries, Nursing Institutions,
The British and Foreign Governments.

Factories: FRAY BENTOS, URUGUAY.

CATTLE FARMS

exceed 1,100 square miles of the finest grazing ground in the world.

The Company are the Sole Manufacturers of these two preparations:

LEMCO a pure, absolutely unflavoured meat extract prepared from the finest beef in the world. It is the original Liebig Company's Extract, the most concentrated form of beef known. There is more beef concentrated in a pound of Lemco than in a pound of any other food in the world. Lemco is specially valuable for invalid cookery and for the preparation of light, nourishing, easily digested dishes. As a sick room food Lemco can be retained by the most delicate stomach when all other food is rejected. It is the most powerful non-alcoholic stimulant known to medical science; its use is immediately followed by increased cardiac power.

OXO a specially prepared amalgamation of Meat Extract and Meat Fibrine. This article is delicately seasoned to tempt the appetite of invalids and convalescents who prefer a flavoured beverage to an unflavoured meat extract.

NEURILLA

FOR NERVOUSNESS

Contains the Essential (anti-nervous) Active Principles of SCUTELLARIA and AROMATICS.

THE IDEAL NERVE CALMANT.

Absolutely harmless even under prolonged use.

DOSE:—FOR ACUTE NERVOUSNESS from Excitement, Fevers, Menstrual Periods, Colds, La Grippe, Childbirth, &c., one teaspoonful every hour, or, in bad cases, every half-hour until improvement; then four times a day.
CHRONIC NERVOUSNESS from Uterine Diseases, Menopause, &c., teaspoonful four times a day.
TEETHING CHILDREN, ten to thirty drops as often as may be indicated.

8 oz. Bottle, 4s. 6d. Retail. Usual Discount to Profession.

Sold by ROBERTS & CO., 76 New Bond Street, London, W., and all Chemists and Druggists.

DAD CHEMICAL CO., New York, U.S.A.

NO OTHER PEPSINE

Has given so great satisfaction to both Prescriber and Patient for twenty years past.

Schacht's Fluid Pepsine

PEPSINA LIQUIDA
(SCHACHT).

One Teaspoonful will Peptonise 1,000 grains of Albumen.

The LANCET reports: "The preparation is decidedly elegant, and possesses great therapeutic powers."

The BRITISH MEDICAL JOURNAL says: "We find by experiment that it has the peptonizing power claimed for it by the makers."

The PRESS & CIRCULAR, October 10th, 1900: "On applying the test to Pepsina Liquida the albumen was completely converted, thus fulfilling the manufacturers' claim. The flavour of the preparation is particularly agreeable."

THE ADULT DOSE IS A TEASPOONFUL, WITH FOOD. REACTION, ACID.

In 4 oz., 8 oz., and 16 oz. bottles, of every Wholesale House,

OR DIRECT FROM

GILES, SCHACHT & Co., CLIFTON, BRISTOL.

"The Lancet," 22nd July, 1899, says:—

"This brandy shows excellent features on analysis while the evidence of taste is distinctly in favour of the description that it is an old matured grape spirit. It possesses that ethereal fragrance due to the peculiar ethers of wine. Our analysis yielded the following results:—Alcohol, by weight 41·00 per cent., by volume 48·43 per cent., equal to proof spirit 84·87 per cent.; acidity expressed as acetic acid, 0·033 per cent.; extractives 0·69 per cent.; mineral matter, *nil*; alcohol in volatile ethers, two grammes per 10 litres. The flavour is soft and mellow and the aroma is characteristic of a sound and mature wine-derived spirit. In view of these analytical and general evidences this brandy may be described as particularly suitable for medicinal purposes."

MARTELL'S

THREE STAR

BRANDY.

"The Medical Press," 2nd August, 1899, says:—

"We have carefully examined a sample of this well-known spirit by the usual tests, and the results obtained by analysis fully warrant our recommending it for medical and dietetic purposes. The analysis gave the following figures:—

Alcohol (as proof spirit)	86·5 per cent.
Extractives	·68 „ „
Ash	Nil.
Acidity	·036 „ „
Ethers (as alcohol)	·028 „ „

"We analysed this product some ten or more years ago, and finding that it still maintains its exceptionally high character, we are consequently in a position to speak highly of it as a genuine old brandy made from wine, well matured, and free from all compounds which might detract from its value as a medicinal agent."

SOLOID BRAND

TRADE MARK.

PRODUCTS.

The use of freshly prepared antiseptic, anæsthetic or astringent solutions is a feature of modern medical and surgical practice. 'SOLOID' PRODUCTS made it a possibility. They contain accurate quantities of active ingredients, and are compact and portable.

'SOLOID' CARBOLIC ACID. The melting point of the pure, crystallised phenol used in this preparation is 104° F. (40° C.)

Supplied to the medical profession, as follows: gr. 5, tubes of 25, 5d.; gr. 20, tubes of 12, 6d.; gr. 60, tubes of 6, 7d per tube.

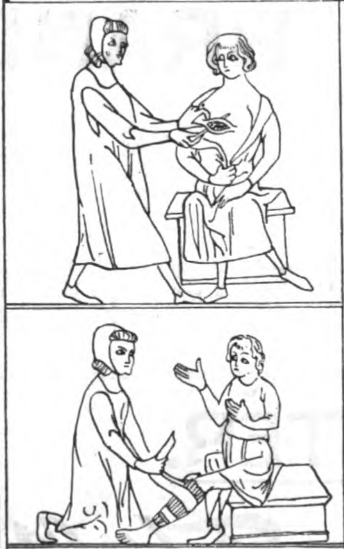
'SOLOID' MERCURIC POTASSIUM IODIDE. (*Formerly known as* IODIC-HYDRARG.) Permits the preparation of fresh solutions possessing the powerful antiseptic properties of mercuric biniodide.

Supplied to the medical profession, in bottles of 25 and 100, gr. 1, 6d. and 1/2; and gr. 8.75, 1/6 and 5/- per bottle.

AVOID IMITATIONS.

BURROUGHS WELLCOME & CO.

LONDON, SYDNEY AND CAPE TOWN.



A guild of surgeons, distinct from the guild of barbers, existed in London from a very early period The earliest mention of it appears in 1369. About this period all external wounds and injuries were attended to by the surgeons, while the treatment of internal diseases became the exclusive province of the priest physicians. The above drawings from an early MS. show an operation being performed on the breast, and the application of splints to a fractured leg.

ROMAN SERIES—7

'KEPLER' MALT EXTRACT

If the prescription reads "*Ext. Malti*" only, the patient may get a sound product or he may not.

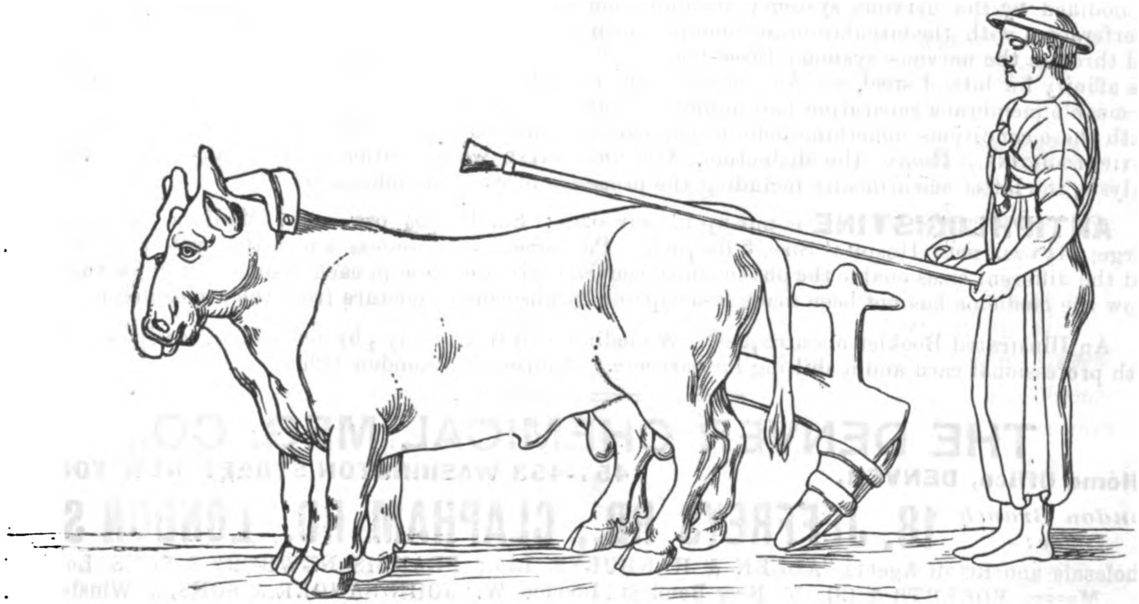
The addition of the word '*KEPLER*' eliminates the element of doubt.

It secures the use of the best malt extract that is made.

Having prescribed 'KEPLER' MALT EXTRACT, it is necessary to see that the patient gets 'KEPLER' MALT EXTRACT. There are imitations.

'Kepler' Malt Extract is supplied to the medical profession in bottles at 1/8 and 3/- per bottle.

BURROUGHS WELLCOME AND CO.,
LONDON, SYDNEY & CAPE TOWN.



4

The Roman husbandman was thus adjured by an antient poet—

"E'v'n in this early dawning of the year, Produce the plough, and yoke the sturdy steer,
And goad him till he groans beneath his toil, Till the bright share is buried in the soil."

[COPYRIGHT]

HYGROSCOPIC
ANTISEPTIC

EXOSMOTIC
ENDOSMOTIC

ANTIPHLOGISTINE

Is an external application for inflammation and congestion. It is a perfectly harmless, soft and pliable, non-irritating, non-toxic, soothing, and antiseptic poultice and surgical dressing always ready for immediate use, possessing hygroscopic, nutrient, exosmotic, endosmotic, and indirectly anodyne and hypnotic properties, and is acknowledged by most of the physicians in the United States, where it has been used extensively for the past ten years, to be the very best local treatment for

PNEUMONIA
PLEURISY
INFLAMED GLANDS
SPRAINS
BRUISES
BOILS
BRONCHITIS
ERYSIPELAS
PERIOSTITIS
SYNOVITIS
FELONS
CHRONIC ULCERS

And for all other cases where INFLAMMATION or CONGESTION is present and a local medicine is indicated.

ANTIPHLOGISTINE is composed of chemically pure glycerine, boric acid, salicylic acid, iron carbonate, peppermint, gaultheria, eucalyptus, and iodine, combined with the base, dehydrated silicate of alumina and magnesia.

Directions.—Warm, then spread about an eighth of an inch (the thicker the better) on the skin over the inflamed part and cover with cotton or heavy cloth. It is sometimes more convenient, especially where the part to be dressed is sensitive, to first spread on cloth, then apply gently. In from 12 to 36 hours it will peel off nicely, like the peel from a banana. Much depends upon properly applying. In mild bronchial affections the chest only need be dressed; in inflammation of the bowels the entire abdomen should be covered; in affections of the joints it should be applied about the joint and several inches above and below; in leg ulcers the indurated and swollen tissues should be covered, and in double pneumonia the entire thoracic walls.

SCIENTIFIC, not EMPIRICAL.—Antiphlogistine was built up or created to meet and scientifically counteract the essential abnormal conditions present in all forms of inflammation. The theory of its action is based largely upon these truths. The food supply of each and every cell of which the body is made is the blood; the vascular system constitutes the highways upon which or through which the food is carried or delivered to each cell, and the functions of this system are presided over, controlled or modified by the nervous system; inflammation means certain definite successional deviations or interferences with the circulation in some part or parts; Antiphlogistine acts upon the vascular system and through the nervous system; three-fourths of the weight of the body is blood-water; as a magnet has affinity for bits of steel, so Antiphlogistine has affinity for water; the skin may be regarded as a permeable membrane separating two liquids of different densities—the blood and the Antiphlogistine. With these conditions something definite happens—an interchange of fluids, most marked towards the Antiphlogistine. Hence, the deduction, Antiphlogistine works through reflex action and through dialysis, the latter scientifically including the processes of ex- and endosmosis.

ANTIPHLOGISTINE is put up in four sizes: Small, 10½ ozs., net; Medium, 17½ ozs., net; Large, 34½ ozs., net; Hospital Size, 5 lbs., net. Packages are seamless and sealed, yet easily opened, and the different sizes enable the physician to conveniently prescribe in each instance a full package, and know the medicine has not been made less capable by absorbing moisture from the atmosphere.

An Illustrated Booklet upon request. A medium can free to any physician upon receipt of request with professional card and a shilling for carriage. Address our London Office.

NESTLÉ'S FOOD

An ENTIRE DIET for INFANTS.

Supplies all the elements necessary for the complete nourishment and growth of the human frame.

Nestlé's Food, being partly composed of milk, is complete and entire in itself and requires simply the addition of water to make it instantly ready for use. It is not merely an auxiliary, like other Infants' Foods which require milk to be added in preparing for use.

Recommended by the highest Medical Authorities as the nearest equivalent to Mother's Milk.

Sample Tin, with Medical Testimony, sent free in the British Isles on application to
H. Nestlé, 48 Cannon Street, London, E.C.

Contains
a Concentrated Preparation of
Fresh Eggs
combined with
Extract of Malt.

'MALTOVA'
a most concentrated and highly nutritive combination of the natural proteids of egg—viz., Albumin, Vitellin, Lecithin, and Nuclein, besides the various salts and elements necessary for building up the human frame.

MALTOVA
PREPARED IN VACUO

Trade Mark.

'MALTOVA'
can be safely taken when other foods cannot be given.

INVALUABLE as a FOOD in all Fever Cases.

Used with any Farinaceous Food it ensures rapid digestion.

THE LANCET, MAY 24, 1902, says:—' The combination of an active malt extract with raw eggs is an excellent idea. Such a preparation is calculated to contain all classes of material suited for the repair of the body waste. Moreover, the combination, of course, contains lecithin, that curious phosphorised principle of nerve substance, brain, &c. That '**Maltova**' is a genuine preparation is obvious from the facts: (1) that it readily transforms starch into sugar, and (2) that it yields a coagulum of albumin on boil-
The preparation is one of undoubted merit, and may be justly reckoned as belonging to the class of specially nutritious foods.

Price 1s. 6d. per 8 oz. bottle, from all Chemists and Druggists, or 1s. 9d. post free,
direct from MALTOVA, LD., 11 New Station Street, Leeds.

Samples and fuller particulars, with Analysts' Reports, &c., gladly sent on application to the Company.

in Anæmia, Neurasthenia, Bronchitis, and Influenza, and during Convalescence from exhausting diseases.

It contains—Hypophosphites of Iron, Quinine, Strychnine, Lime, Manganese, and Potash. Each fluid drachm contains the equivalent of 1-64th grain of pure Strychnine.

SPECIAL NOTE.—Fellows' Syrup of Hypophosphites is NEVER SOLD IN BULK, and is advertised only to the Medical Profession. Physicians are cautioned against worthless substitutes.

Medical Letters may be addressed to—

Mr. FELLOWS, 94 Paul Street, Finsbury, London E.C.

LITERATURE OF VALUE WILL BE SENT ON APPLICATION

Doctors should be aware that

INVALID BOVRIL

is a special preparation, quite distinct from ordinary Bovril, and more highly concentrated. It is

UNSEASONED,

and consequently acceptable to the most fastidious palate. For patients who object to Bovril on account of its salt flavour, Doctors might order INVALID BOVRIL, which can be obtained from any Chemist.

THE LANCET, writing of two Special Analyses—

the first an analysis of Special Invalid Bovril, and the second, one of a good home made beef-tea—remarks that in considering the question of relative nutriment, regard must, of course, be paid to the amount of water employed in preparing beef-tea, and says very forcibly that "All things being equal, the Invalid Bovril yielded, according to the analysis from THE LANCET Laboratory, a much higher proportion of nutrient substance than the ordinary beef-tea."

As recommended and so successfully used by Dr. Minchin for the treatment of Pulmonary Tuberculosis. Full directions accompany each bottle. Price, 10/6 per 2-oz. bottle. Special 8-oz. bottles for the Profession and Dispensing Purposes, 21/- each. To be obtained at

THE MEDICAL HALL, Church Street, Kells., Co. Meath.

Applications for the treatment of Surgical Cases of Tuberculosis and Lupus can also be had.

ALTADORE SANATORIUM, DELGANY, co. WICKLOW.

For the treatment of Diseases of the Lungs on the Nordrach System.

This Sanatorium is delightfully situated among the Wicklow Mountains. The house, which stands in its own grounds of nearly 600 acres, is 750 feet above sea level, and is well protected on the north, east, and west, while to the south it commands a fine view of the sea, some 5 miles distant. It thus combines the advantages of pure mountain air and pure sea air. Excellent diet. Milk from own tuberculin-tested cows. The Sanatorium is in the charge of a physician who acquired his knowledge of the treatment at Nordrach, under Dr. Otto Walther, and who has met with great success in carrying out Dr. Walther's principles. For terms and prospectus apply to the Resident Physician, J. C. SMYTH, M.R.C.S.Eng., L.R.C.P.Lond. (late of Glastonbury, Somerset). Postal Address: Altadore, Kilpedder, co. Wicklow. Telegraphic Address: Altadore, Newtownmountkennedy, co. Wicklow. Railway Station: Greystones.

FRIDAYS,

THE RETREAT PRIVATE ASYLUM

Near Armagh

(ESTABLISHED 1824.)

Licensed for the reception of ladies and gentlemen of the upper and middle classes suffering from

MENTAL AND NERVOUS DISEASES.

(Voluntary Boarders and Inebriates admitted). This establishment has lately undergone many structural alterations and improvements, and the walks and grounds are extensive and picturesque.

Great care and attention are bestowed upon the patients; outdoor and indoor games and regular carriage exercise being provided.

Golf links have been recently added.

For further information apply to the Medical Superintendent, Dr J. GOWER ALLEN J.P., or Mr. JOSEPH ALLEN, Clonallen, Armagh.

ST. PATRICK'S HOSPITAL FOR MENTAL DISEASES.

The Governors of ST. PATRICK'S HOSPITAL, DUBLIN (founded by Dean SWIFT in 1745), wish to announce that they have acquired a large property, in accordance with their Royal Charter (200 acres), and established a Private Asylum in connection with the Hospitals at Lucan, for the reception of Lady patients suffering from Mental Disease.

The house, which contains ample accommodation, stands on one of the most beautiful sites in the County, and is surrounded by a demesne of 200 acres, including charming pleasure grounds and gardens.

No expense has been spared in bringing the establishment in every respect up to the level of the leading asylums of the United Kingdom.

A separate Resident Medical Superintendent and experienced Nursing Staff is provided.

The parent institution in Dublin continues its curative work, has undergone almost entire reconstruction, receives both male and female patients, and its recovery rate is very satisfactory. The Governors are anxious that the Medical Profession should be acquainted with the work of this historic institution, which has been devoted, for over a century and a-half, to the reception and curative treatment of the insane of Ireland.

For further particulars application should be made to the REGISTRAR, St Patrick's Hospital, James Street, Dublin.

SOLUBLE COATED PILLS **Pills and their Coating.**—An experience of over a quarter of a century has demonstrated that sugar, as applied by our process without heat, is the most suitable and soluble substance for coating pills. In this assertion we are sustained by the highest authorities, who have tried them repeatedly and verified our claims. Our principal claims are solubility and compatibility under all circumstances.

CASCARA ELIXIR Disappointment in the use of Cascara preparations has resulted from employing an inferior drug, or from an unstable preparation. The Elixir prepared by W. R. W. & Co. is **palatable** and **reliable,** and of reasonable price. Its pleasant taste, free from the characteristic bitterness of the drug, renders it peculiarly acceptable to ladies and children.

BROMO SODA **(Registered).** Bromide of Sodium with Caffeine, in granular form. Very carefully and evenly made. Invaluable in Brain Fatigue arising from Overwork, &c. The *Lancet* (Aug. 6, 1887, p. 265) stated that "the sodium compound does, in fact, agree better (than the potassium salt) with some stomachs." Per bottle, **3s. 6d.**

TONO SUMBUL "Tono Sumbul" combines the well-known and positive **NERVE TONIC** and **STIMULANT** properties of **SUMBUL ROOT,** the **BLOOD MAKING** properties of **IRON,** and the general system-tonic and antiperiodic qualities of **CINCHONA BARK,** together with acid phosphates, &c., so blended with delightful aromatics as to present a cordial which is both palatable and wonderfully efficient in allaying the troubles for which it is intended. (**3s. 6d.**)

INGLUVIN **(Registered)** A Powder. The essential principle of the gizzard, and bearing the same relation to poultry that pepsin does to the higher animals. Where pepsin refuses to act, and where, in severe cases, it has even been rejected by the stomach, **Ingluvin has effected relief** rapidly and with ease. Also in compressed form, and in 4-oz. bulk bottles for Dispensing.

OBESITY TABLETS Dr. Cathell has discovered that the administration of Kissingen Water and Vichy Water, taken alternately, is a **reliable** and **harmless** means for diminishing or curing over-fatness. These salts, in compressed tablets, are presented in a suitable box with appropriate literature. (Retail price **2s.**)

Samples, Pamphlets, &c., free on request.

British Depot: **F. NEWBERY & SONS** (Established 1746), 27 & 28 Charterhouse Sq., LONDON, E.C.

LIQUOR PEPSINÆ (EARL).

This well-known remedial and curative preparation was originated by the late P. W. EARL, Analytical Chemist, in 1885. Since then it has been materially improved in its mode of manufacture, and notwithstanding the fact that the market is flooded at present with preparations of Pepsine, none of them are more certain or reliable in their action, and few to be at all compared to it. It is largely prescribed by the medical faculty in all cases of Indigestion and Dyspepsia, whether recent or chronic, and being so palatable and agreeable in taste is peculiarly suitable for Children of all ages.

It is carefully prepared from fresh, healthy maws under the immediate supervision of the owner, who is a qualified chemist.

ANALYTICAL AND MEDICAL OPINIONS.

Sir CHARLES A. CAMERON, M.D.—"*A reliable remedy for indigestion and dyspepsia.*"
Sir GEORGE H. PORTER, M.D.—"*I have found it a most efficient remedy.*"
Sir WILLIAM STOKES, M.D.—"*A most useful, agreeable, and efficacious preparation.*"

LOWER SACKVILLE ST., 107 GRAFTON ST., DUBLIN; RATHMINES TERRACE RATHMINES;
AND 102 UPPER GEORGE STREET, KINGSTOWN.

THE TASTELESS AND BEST NATURAL APERIENT.

Æsculap

"Contains the Sulphates of Magnesium and Sodium in unusually large quantities. It is an admirable aperient water."—THE LANCET.

"ÆSCULAP is the clearest and purest of all the Hungarian Aperient Waters."—THE HOSPITAL.

"Of uniform strength and free from organic impurity."—EDINBURGH MEDICAL JOURNAL.

"A valuable remedial agent in stomach and intestinal affections."—GLASGOW MEDICAL JOURNAL.

"It is an efficient aperient."—DUBLIN JOURNAL OF MEDICAL SCIENCE.

"It possesses the decided advantage of being less unpleasant to take than many other bitter waters, as well as being free from any organic impurity."—THE MEDICAL PRESS.
